

YETI 2021 The Future of Lepton Colliders

Future Collider Technologies and their challenges

Stephen Gibson RHUL 9th July 2021

Overview

- Motivation
 - Accelerators drive discoveries
 - What technologies will improve the state-of-the-art?
- Near-future
 - High-Luminosity LHC
 - Technical capabilities to address future challenges
- Mid-future
 - Linear Colliders: ILC & CLIC
 - Future Circular Colliders: FCCee & CEPC
- Further-future
 - Muon Collider
 - Advanced acceleration:
 - Laser & beam driven wakefield; THz; dielectric...
- Dream beams

Motivation

• How to address the fundamental questions of particle physics?

- Why do we observe three generations of quarks and leptons?
- Are there particles or interactions Beyond the Standard Model?
- Why is there a matter-antimatter asymmetry in the universe?
- What is mass? How exactly is electroweak symmetry broken?
- What is the nature of Dark Matter? Are there Extra Dimensions?

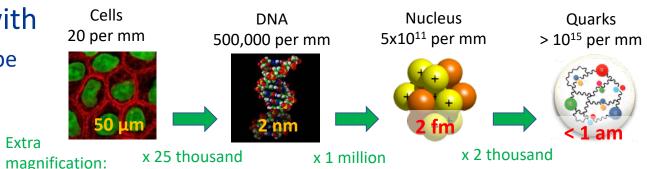

Accelerators enable us to collide particles with

 the energy to create new, massive particles, or to probe matter at the smallest length scales,

De Broglie
$$\lambda = \frac{h}{p}$$
 wavelength

and the luminosity required to observe rare processes:

$$\mathcal{L} = \frac{1}{\sigma} \frac{dN}{dt} = \frac{N_1 N_2 f N_b}{4\pi \sigma_x \sigma_y}$$

Microscope

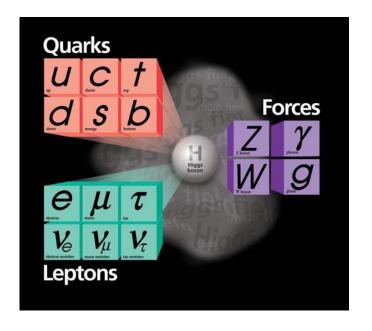

Electron microscope

Particle accelerators

• Advancement in accelerator technology drives discoveries, e.g.:

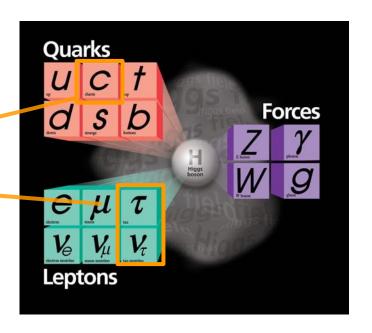

• Advancement in accelerator technology drives discoveries, e.g.:

Electron-positron storage ring, SPEAR, facilitated discovery of charmonium, J/ψ , and τ lepton.

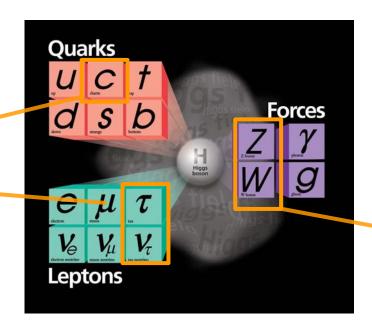

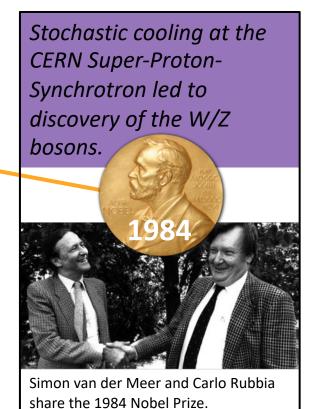

Advancement in accelerator technology drives discoveries, e.g.:

Powerful superconducting coils at the Tevatron enabled the top quark discovery

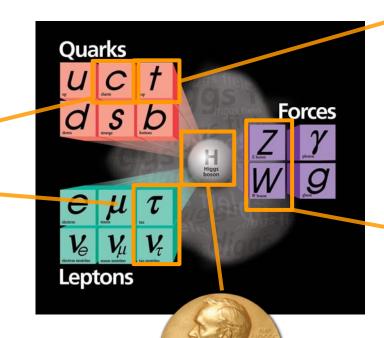

Advancement in accelerator technology drives discoveries, e.g.:

Electron-positron storage ring, SPEAR, facilitated discovery of charmonium, J/ψ , and τ lepton.

A giant leap in energy and **luminosity** at the Large Hadron Collider delivered the long-awaited Higgs Boson

Peter Higgs and Francois Englert

Powerful superconducting coils at the Tevatron enabled the top quark discovery

> Stochastic cooling at the CERN Super-Proton-Synchrotron led to discovery of the W/Z bosons.

Simon van der Meer and Carlo Rubbia share the 1984 Nobel Prize.

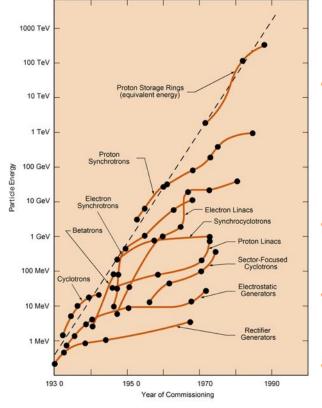

share the 2013 Nobel Prize

"Livingston" plots of accelerator development

 Since 1930 there has been about a factor 10 increase in equivalent fixed-target energy, every 6-8 years:

From W.K.H. Panofsky, "Evolution of Particle Accelerators and Colliders 1997.

- As one technology "ran out of steam", another technology took over!
- Recently, this trend has softened:
- What limits the energy reach of current machines?
 - What are the breakthrough technologies needed for future accelerators?

Jordan Nash, Imperial College London, Current and Future Developments in Accelerator Facilities, 2010 IOP Meeting

What limits the energy reach of circular colliders?

• Synchrotron radiation

- Charged particles accelerated transversely in a curved trajectory by a magnetic field emit synchrotron radiation:
- The total power radiated by synchrotron emission for a single charged particle, P_s is:

$$P_{\rm s} = \frac{e^2 c}{6\pi\epsilon_0} \times \frac{\gamma^4}{R^2}.$$

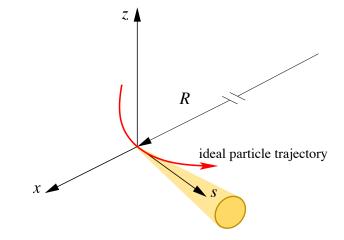

See Appendix 1.1 &1.2 of **Wilson** for derivation from retarded fields

Where:

e is the electron charge c is the speed of light

R is the radius of the charge particle's orbit $\gamma = \frac{E}{m_0c^2} \text{ is the ratio of the particle's total energy to its rest mass energy}$

$$P_s \propto \frac{\gamma^4}{R^2} \sim \frac{E^4}{m^4} \times \frac{1}{R^2}$$

– Energy lost per turn:

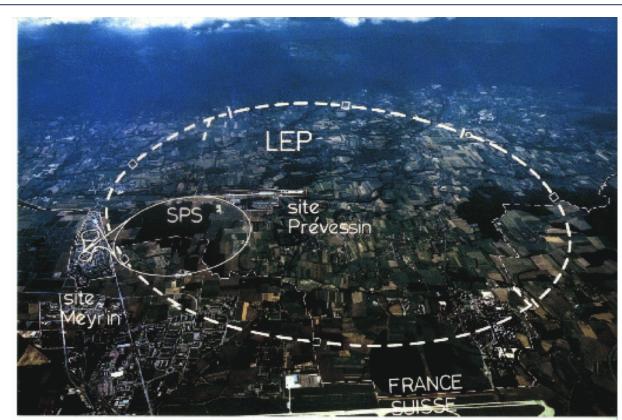

$$\Delta E_{\rm s} = \oint P_{\rm s} dt = P_{\rm s} t_{\rm b} = P_{\rm s} \frac{2\pi R}{c}$$

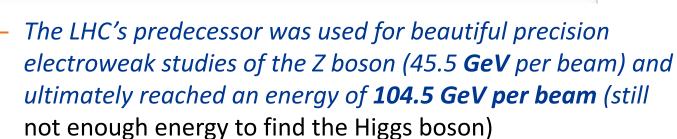

$$\Delta E_{\rm s} = \frac{e^2}{3\epsilon_0} \times \frac{E^4}{(mc^2)^4} \times \frac{1}{R}$$

- This lost energy must be replenished by further acceleration
- Synchrotron radiation limits the maximum energy that is attainable in high energy circular accelerators, particularly for electron synchrotrons, due to small m_e 0.511 MeV/c²

The Large Electron-Positron Collider, 1989-2000

Excitement as LEP2 breaks the energy record, 100 GeV per beam: (while I was a summer student in 1999!)

How to beat the synchrotron limit?

$$\Delta E_{\rm s} = \frac{e^2}{3\epsilon_0} \times \frac{E^4}{(mc^2)^4} \times \frac{1}{R}$$

Increase m, same R: reuse LEP tunnel with protons -> LHC,

and in near future:

switch to higher lepton mass

Challenge is to produce and capture intense beams of short-lived muons

increase R

FCChh in 100 km tunnel requires high-field magnets

set R to infinity

Linear colliders require **high** gradient acceleration:

SCRF structures, drive beams or advanced accelerator concepts (plasma wakefield)

+ energy recovery linacs

Key technologies for future accelerators

• Five technologies pillars were identified in the 2020 EU strategy and by CERN Council / SPC / LDG.

High-priority future initiatives

- High-field magnets
- High-gradient plasma
 / laser acceleration
- High-gradient RF structures
- Muon beams
- Energy-recovery linacs

- B. Innovative accelerator technology underpins the physics reach of high-energy and high-intensity colliders. It is also a powerful driver for many accelerator-based fields of science and industry. The technologies under consideration include high-field magnets, high-temperature superconductors, plasma wakefield acceleration and other high-gradient accelerating structures, bright muon beams, energy recovery linacs.

 The European particle physics community must intensify accelerator R&D and sustain it with adequate resources. A roadmap should prioritise the technology, taking into account synergies with international partners and other communities such as photon and neutron sources, fusion energy and industry. Deliverables for this decade should be defined in a timely fashion and coordinated among CERN and national laboratories and institutes.
- Current work towards the European accelerator R&D roadmap with an update for the HEP community taking place today:
- 9th July 2021: Symposium on the Accelerator R&D Roadmap for the HEP community
 - https://indico.cern.ch/event/1053889/

The political challenge...

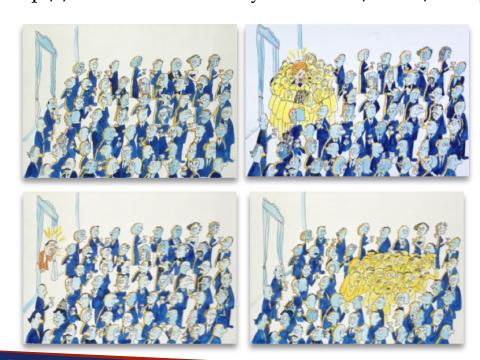

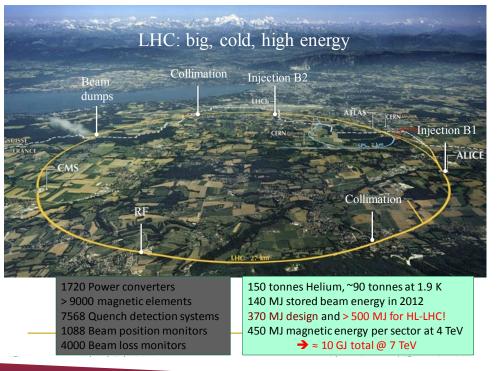

"My Lords, can my noble friend tell us what a Large Hadron Collider is, and whether a smaller one might not do?" - LORD ELTON, July 1994

speaking in the House of Lords debate on the LHC, Hansard, 18th July 1994. The full transcript:

http://hansard.millbanksystems.com/lords/1994/jul/18/large-hadron-collider

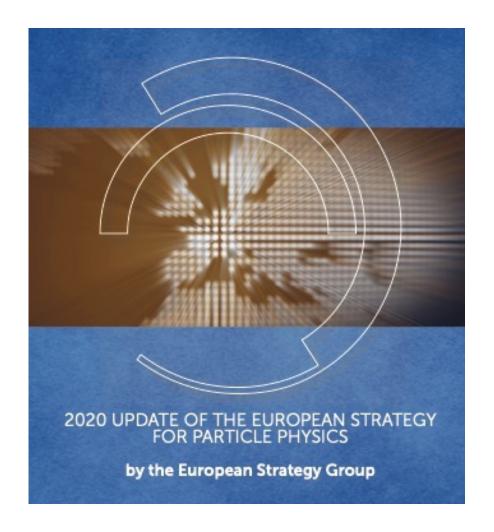

Near future:

High-Luminosity LHC and recently developed technologies applicable to many future accelerators

2020 update of European Strategy

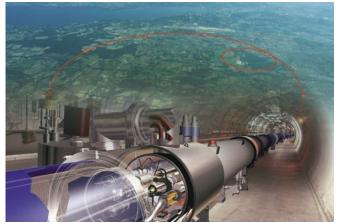

Major developments

their planned detector upgrades, a significantly enhanced physics potential is expected with the HL-LHC. The required high-field superconducting Nb₃Sn magnets have been developed. The successful completion of the high-luminosity upgrade of the machine and detectors should remain the focal point of European particle physics, together with continued innovation in experimental techniques. The full physics potential of the LHC and the HL-LHC, including the study of flavour physics and the quark-gluon plasma, should be exploited.

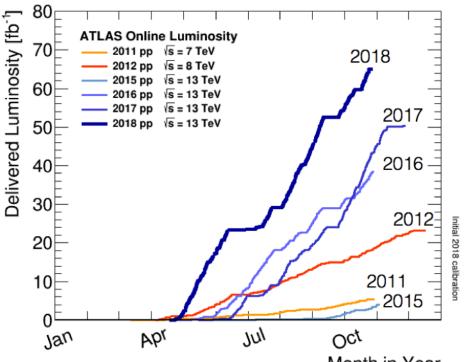

LHC performance and future

LHC performance has exceeded yearly targets in quest to measure Higgs Boson couplings and search for exotic physics:

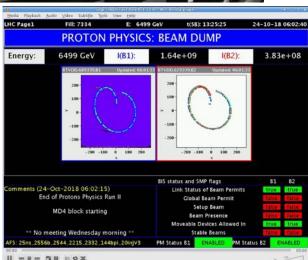

Dark Matter, Extra Dimensions, Super symmetry, ...

Processes extremely rare, requires many collisions = luminosity!

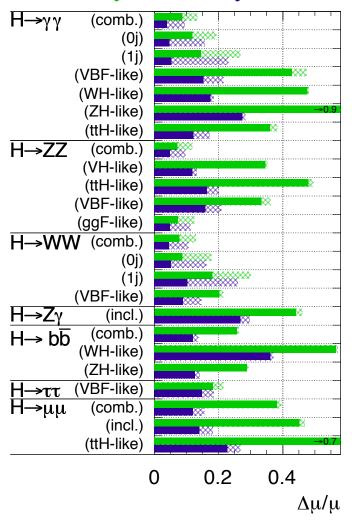

160 fb⁻¹ achieved in Run II

ATLAS Simulation Preliminary

 $\sqrt{s} = 14 \text{ TeV}: \int Ldt = 300 \text{ fb}^{-1}; \int Ldt = 3000 \text{ fb}^{-1}$

The path to High Luminosity LHC

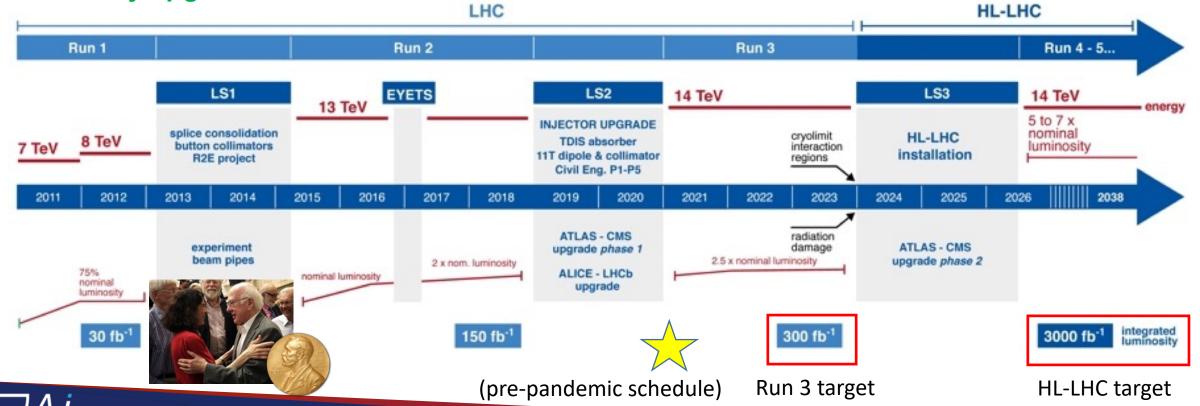

- LHC Run-II at 13 TeV, integrated luminosity of >160 fb⁻¹ delivered to ATLAS/CMS at end 2018.
- Plan to increase to 14 TeV after Long Shutdown 2.

John Adams Institute for Accelerator Science

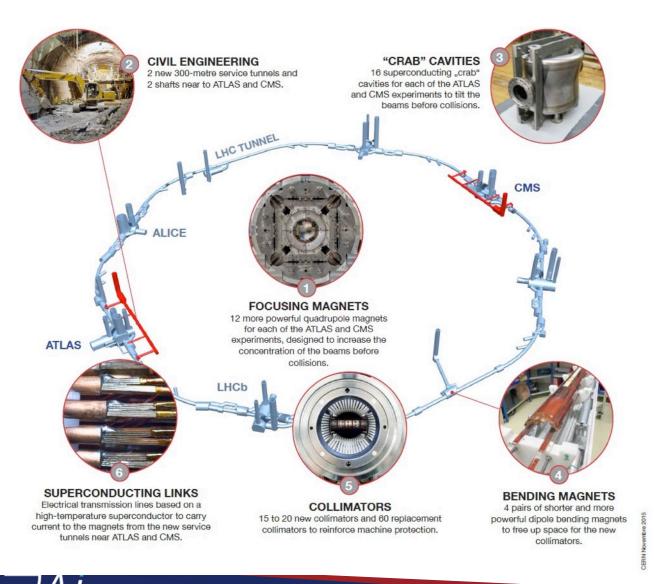

After LS3 ending 2026, enter HL-LHC: aim to reach 5 - 7x nominal luminosity.

 Europe's top priority should be exploitation of the full potential of the LHC, including the high luminosity upgrade of the machine and detectors.

High Luminosity LHC – how?

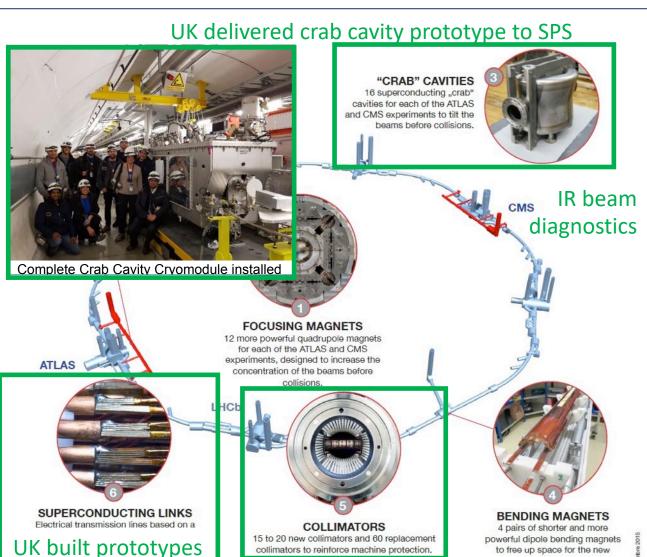

- Lower beta* (~15 cm)
 - New inner triplets wide aperture Nb₃Sn
 - Large aperture NbTi separator magnets
 - Novel optics solutions
- Crossing angle compensation
 - Crab cavities
 - Long-range beam-beam compensation
- Dealing with the regime
 - Collision debris, high radiation
- Beam from injectors
 - Major upgrade of complex (LIU)
 - High bunch population, low emittance, 25 ns beam

HL-LHC-UK phase I (2016-2020)

Major simulation/design effort

UK institutes on **HL-LHC-UK**£8M CERN-STFC investment in UK

+ new injector diagnostics

Linac2: 50 MeV protons

HL-LHC-UK phase II announced by STFC

https://stfc.ukri.org/news/project-to-upgrade-the-large-hadron-collider-now-underway/

Upgrade to Large Hadron Collider underway

11 September 2020

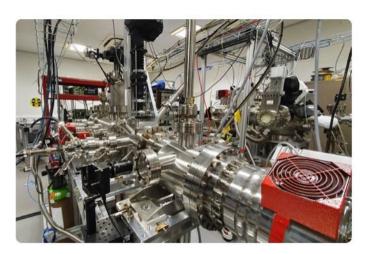

Scientists, engineers and technicians from the UK have embarked on a £26 million project to help upgrade the Large Hadron Collider (LHC) at CERN, on the French/Swiss border near Geneva.

The collaboration is between the Science and Technology Facilities Council (STFC), CERN, the Cockcroft Institute, the John Adams Institute, and eight UK universities. STFC is contributing £13.05 million.

Science Minister Amanda Solloway said:

"Ever since it first switched on in 2008, CERN's Large Hadron Collider has been working to answer some of the most fundamental questions of the universe.

"I am delighted that the UK's science and research industry will play a central role in upgrading what is the world's largest and highest energy particle collider, enabling leading physicists to continue making monumental discoveries."

Gas jet beam profile monitor setup at the Cockcroft Institute.

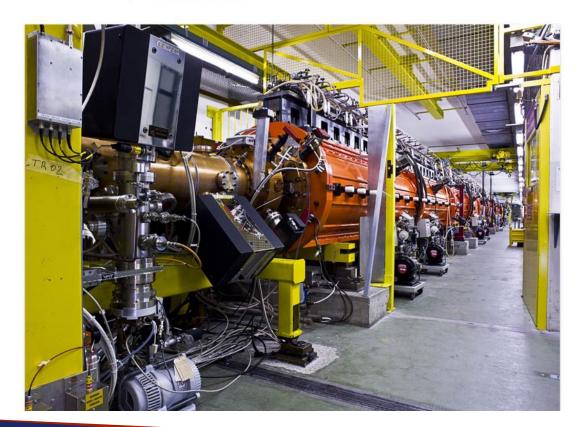

Beam off at Linac2 -> Linac4, a new hope

So long, Linac2, and thanks for all the protons

After 40 years of service, the linear accelerator has shut down and passed the baton to Linac4, which will take over as the first link in the accelerator chain

13 NOVEMBER, 2018 | By Corinne Pralavorio

Frédérick Bordry, Director for Accelerators and Technology, switching off the Linac2 on 12 November. (Image: Nathan Schwerdtel/CERN)

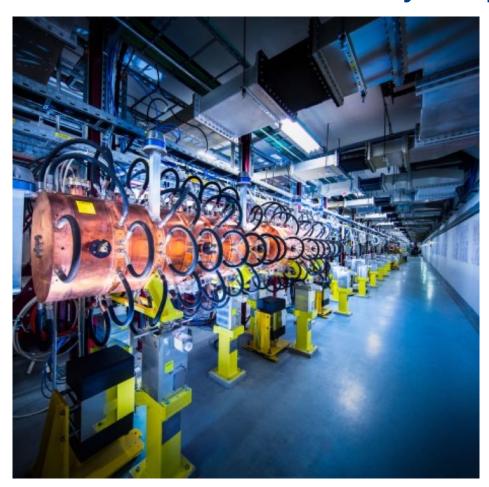

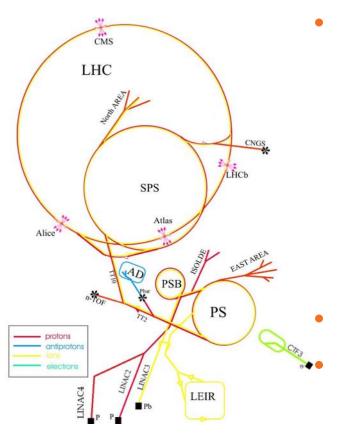

Beam off at Linac2 -> Linac4, a new hope

• Linac4 is now the main injector for LHC, connected to PSB in LS2 2019/20

LHC Injectors Upgrade

- H- ions boosted to 160 MeV
 - 3 MeV, 352MHz Radio-Frequency
 Quadrupole (RFQ)
 - 50 MeV drift tube linacs (DTLs)
 - 100 MeV coupled-cavity drift tube linacs (CCDTLs)
 - 160 MeV Pi-mode structures (PIMS)
 - Commissioned 160 MeV in 2016.
 - Multi-turn H- charge exchange injection to PSB enables a more brilliant beam for HL-LHC.

Why upgrade the injector?

Emittance requirements for HL-LHC bunches cannot be reached with existing machines:

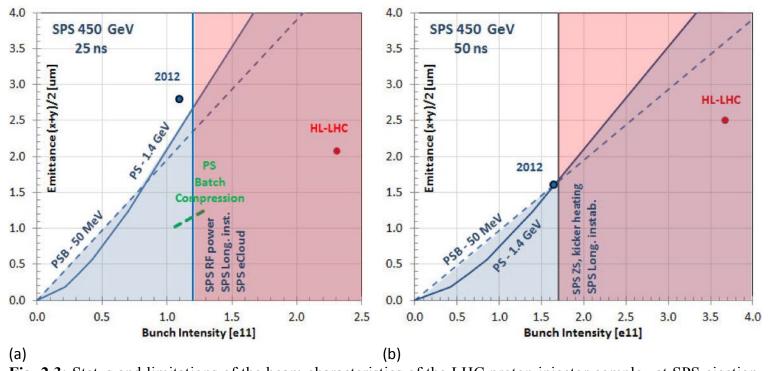

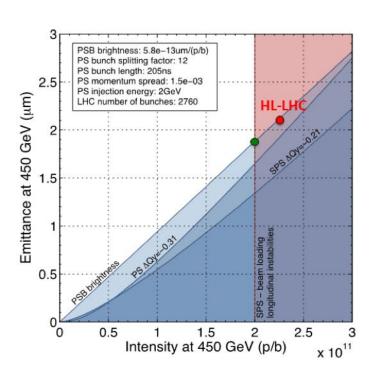

Fig. 2.3: Status and limitations of the beam characteristics of the LHC proton injector complex at SPS ejection, in 2012. (a) 25 ns bunch spacing; (b) 50 ns bunch spacing.

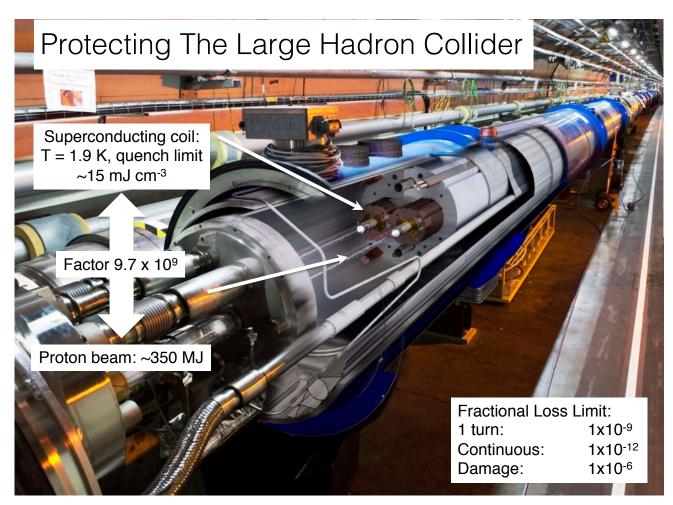

LIU: Technical Design Report, volume 1 protons
CERN-ACC-2014-0337

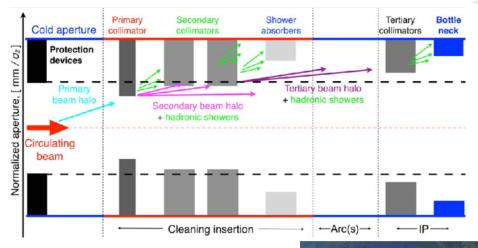

Machine Protection at the LHC, HL-LHC and FCC-hh

LHC Collimation
Project

• Efficient cleaning of proton beam halo is vital to protect the sc magnets

Stored beam energy:

- LHC ~ 350 MJ

TGV at 150km/h

– FCC-hh = 8.4 GJ

Equivalent to AirBus A380 at 850 km/h

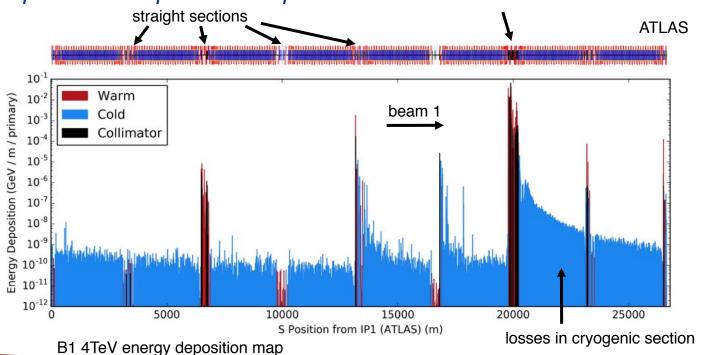

Collimation studies with BDSIM model of (HL-)LHC

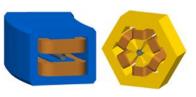

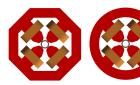

- BDSIM automatically builds a 3D, Geant4 model, from generic accelerator components.
- LHC stores unprecedented energy in beams: 350 MJ (80kg of TNT) stored per beams at design energy (500MJ HL-LHC)
- Halo efficiently cleaned by collimation system
- LHC model developed to simulate collimation and energy deposition. Requires 1:10⁶ precision betatron collimation

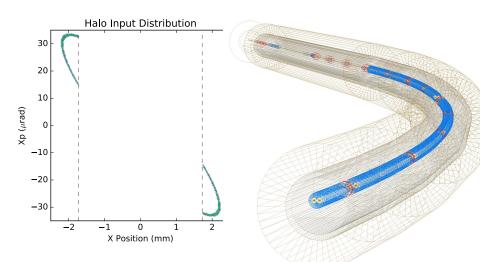

Beam Delivery Simulation

Example halo distribution

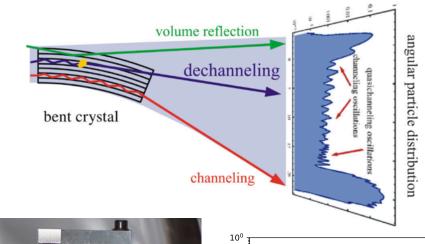

https://doi.org/10.1016/j.cpc.2020.107200

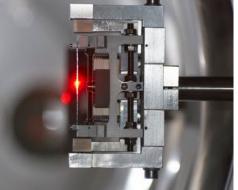

Active halo control & novel collimation

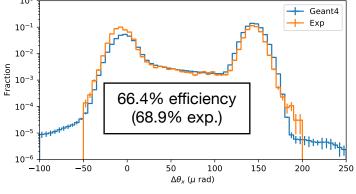

- How can we remove halo particles without affecting the core?
- Novel collimation techniques being developed for HL-LHC:

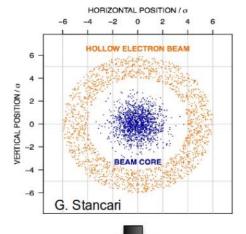

Crystal collimation

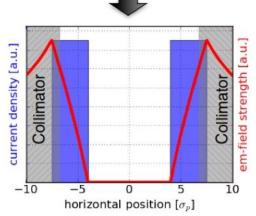

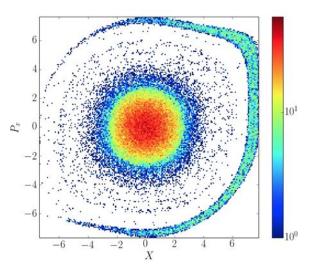

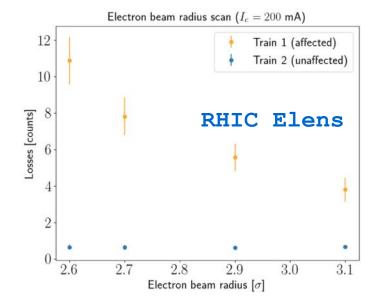

Hollow electron lens

Superconducting RF capabilities

 ASTeC @ Daresbury hosts major facility for SRF design & fabrication for many projects

1 ERL SRF Linac

28

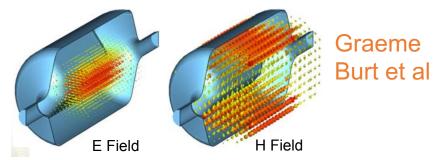

Crab-cavity cryomodules for HL-LHC:

Graeme

UK contributing cryomodules for crab-cavities, which rotate the colliding bunches to increase the luminosity.

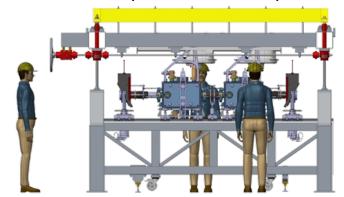

Cleanroom Assembly

Cryomodule Assembly

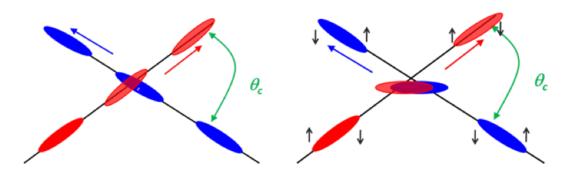

Bunch crabbing for HL-LHC

 LHC luminosity is currently limited by geometrical overlap, due the crossing angle (285mrad) between beams:

$$\mathcal{L} = \frac{N_1 N_2 f N_b}{4\pi \sigma_x \sigma_y} \qquad R(\theta) = \frac{1}{\sqrt{1 + (\frac{\sigma_s}{\sigma_x} tan\frac{\theta}{2})^2}}$$

 At HL-LHC, RF crab cavities will rotate the bunches to collide head on:

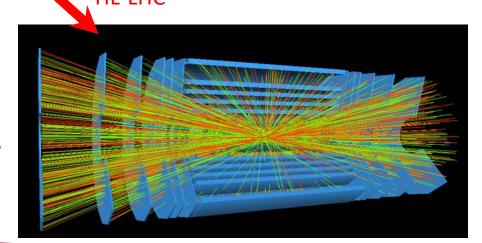

23 interactions per bunch crossing at nominal LHC

One bunch crossing in the ATLAS particle tracker

Z→µµ event from 2012 data with 25 vertices

HL-LHC: pile up increases to ~140 vertices per crossing.

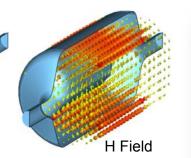

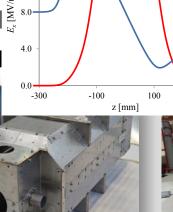

Demonstration of HL-LHC crab-cavities

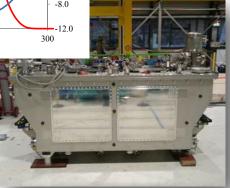

- First prototype cryomodule (DQW) tests completed on SPS in mid 2018.
- First ever evaluation of crab cavities with a proton beam!
- A 2-cavity pre-series RFD cryomodule in development + providing 4 production DQW cryomodules for LS3

nostics and

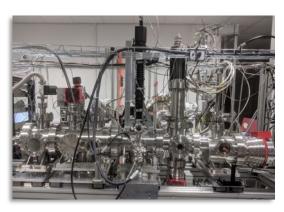

E Field

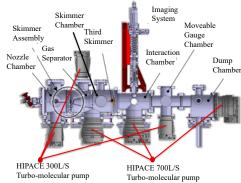

Beam diagnostics for FCC-hh (developed for HL-LHC)

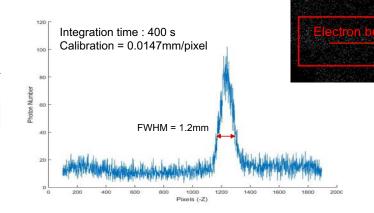

- Fully characterizing FCC-hh circulating beams with high intensity requires similar diagnostics to those being developed for HL-LHC. Examples include:
- Beam-gas interactions:

 Continuous, non-invasive 2D beam profile monitoring by a supersonic gas jet monitor for the hollow electron lens collimation.

- Electro optics techniques:
 - Electro-optic BPM diagnostics for measurement of crabbed rotation of the hadron bunch [RHUL].
 - For FCC-ee, the electron bunch will require sub-ps e-o techniques, as pioneered at ASTeC.

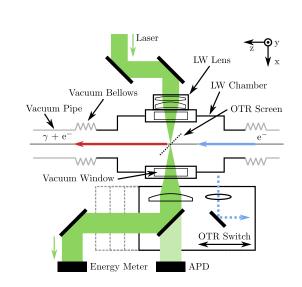

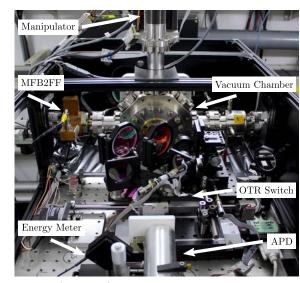

Beam diagnostics for FCC-ee

- Small electron bunches at high energy, and sub ps resolution require novel approaches:
 - To measure small transverse beam sizes, SR interferometric measurements are under development at LHC, though need to be demonstrated for X-ray wavelengths.
 - Bunch lengths of ps, with resolution of 10 fs pose difficulties for streak cameras and e-o sampling techniques due to the relatively long bunch.
 - Non-invasive techniques based on Čerenkov diffraction radiation may results in a directional beam position monitor and for fast intra-bunch transverse instabilities.

- FCC-ee requires polarimetry based on inverse-Compton scattering
 - Similar to implementation at LEP and could leverage expertise on electron laserwires developed for Linear Collider at ATF2 in KEK.

PRSTAB 17, 072802 (2014)

Lase

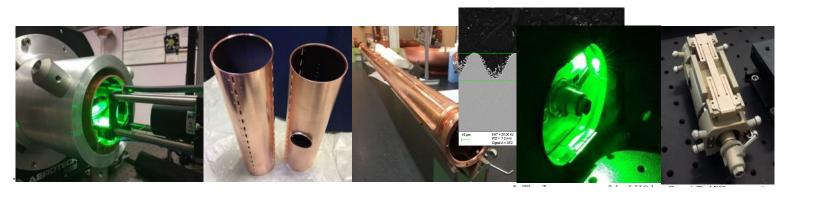

Electron cld

 Secondary electron yield can be suppressed by modifying the surface walls with a laser, creating channels to trap the electrons.

Automated robot for in-situ treatment of beam-screens at HL-LHC:

Capabilities in accelerators & enabling technology

Developing a broad range of UK capabilities to address future technical challenges, including

- Beam dynamics simulations; optical lattice design & optimisation
- Novel collimation techniques: crystal, hollow electron lens.
- Machine detector interface & accelerator backgrounds
- Superconducting RF cavities, crab-cavities, high efficiency klystron development
- Beam diagnostics, including non-invasive profile & bunch instability monitoring
- Nanobeam control and fast feedback
- Cryogenic systems, cold powering.
- Vacuum systems & electron cloud mitigation
- Accelerator alignment systems
- Operational experience of low emittance electron storage rings & FEL test facilities...

ESPP2020 "Innovative accelerator technology underpins the physics reach of high-energy and high-intensity colliders. ... The European particle physics community must intensify accelerator R&D and sustain it with adequate resources.

Mid-future: Higgs Factory: Linear Collider / Future Circular Collider

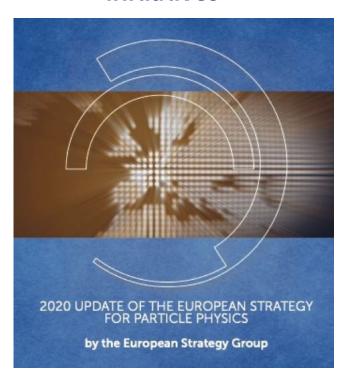

2020 update of European Strategy

High-priority future initiatives

The vision is to prepare a Higgs factory, followed by a future hadron collider with sensitivity to energy scale of order of magnitude higher than those of the LHC, while addressing the assembled technical and environmental challenges

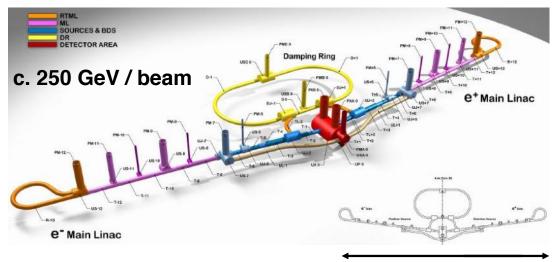

Other essential scientific

A. An electron-positron Higgs factory is the highest-priority next collider. For the longer term, the European particle physics community has the ambition to operate a proton-proton collider at the highest achievable energy. Accomplishing these compelling goals will require innovation and cutting-edge technology:

The timely realisation of the electron-positron International Linear Collider (ILC) in Japan would be compatible with this strategy and, in that case, the European particle physics community would wish to collaborate.

Higgs factory e⁺e⁻ collider for precise measurements of Higgs & top ++, complementary to LHC

31 km

• ILC TDR complete, mature technology with many benefits:

- Well defined centre of mass energy: 2E
- complete control of event kinematics: p = 0, M = 2E
- polarised beam(s)
- clean experimental environment

ICFA announces a new phase towards preparation for the International Linear Collider

At its 86th meeting held today, ICFA approved the formation of the International Linear Collider International Development Team as the first step towards the preparatory phase of the ILC project, with a mandate to make preparations for the ILC Pre-Lab in Japan.

A description of the mandate and structure of the ILC International Development Team was also approved by ICFA today.

The Team will commence its work immediately and is expected to complete it by the end of 2021.

The ILC International Development Team will work towards making a timely realization of the ILC possible.

ICFA thanks the Linear Collider Collaboration led by Dr. Lyn Evans for its excellent work over the past several years.

CLIC summary

• Timeline: e+e- linear collider at CERN for the era beyond HL-LHC

• Compact: novel and unique two-beam accelerating technique based on

high-gradient room temperature RF cavities:

first stage: 380 GeV, ~11km long, 20,500 cavities

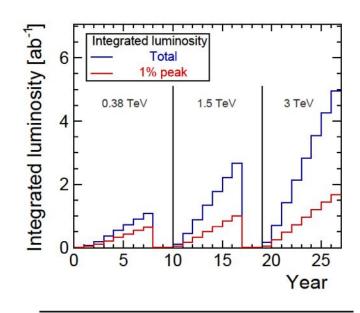

• Expandable: staged collision energies from 380 GeV (Higgs/top) up to 3 TeV

Conceptual Design Report published in 2012

Project Implementation Plan released 2018

Cost: 5.9 BChF for 380 GeV (stable w.r.t. CDR)

Power: 168 MW at 380 GeV (significantly reduced since CDR)

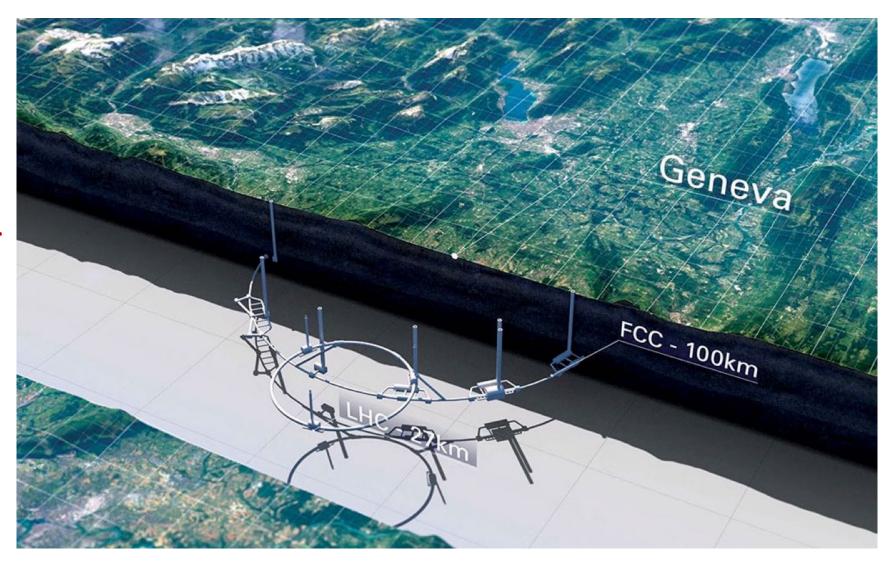

Stage	\sqrt{s} [TeV]	\mathcal{L}_{int} [ab ⁻¹]
1	0.38 (and 0.35)	1.0
2	1.5	2.5
3	3.0	5.0

Baseline polarisation scenario adopted: electron beam (–80%, +80%) polarised in ratio (50:50) at \sqrt{s} =380GeV; (80:20) at \sqrt{s} =1.5 and 3TeV

Future Circular Collider

ESPP20 update and next steps for FCC

• *EU Strategy 2020:*

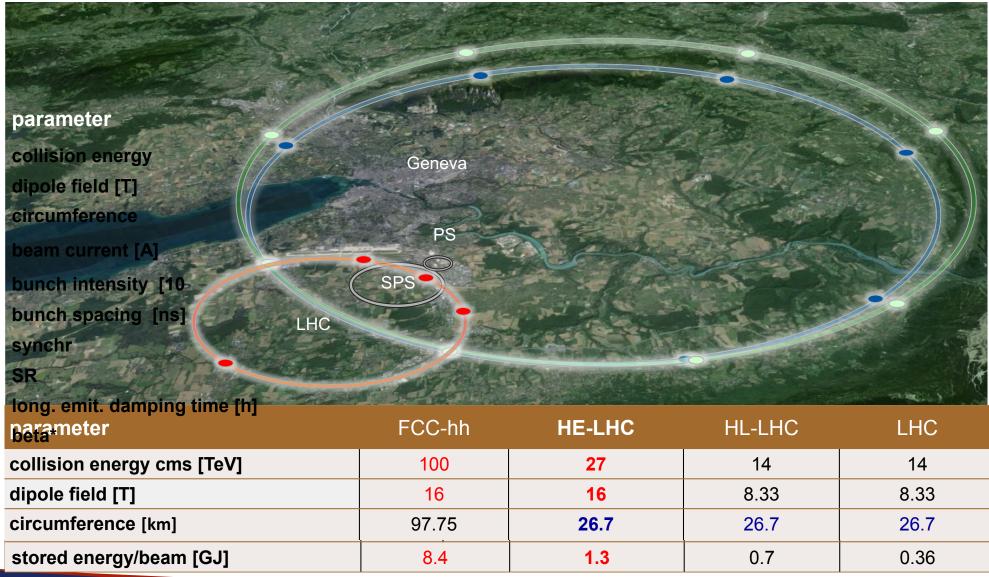

"Europe, together with its international partners, should investigate the technical and financial feasibility of a future hadron collider at CERN with a centre-of-mass energy of at least 100 TeV and with an electron-positron Higgs and electroweak factory as a possible first stage. Such a feasibility study of the colliders and related infrastructure should be established as a global endeavour and be completed on the timescale of the next Strategy update."

- FCC Innovation Study (FCCIS) kickoff meeting in 9-13 November 2020 at CERN, including 4th Physics & Experiments workshop, beginning to address the ESPP20 mandate.
 - https://indico.cern.ch/event/923801/
 - FCCIS will deliver a conceptual design and an implementation plan for a new research infrastructure, consisting of a 100 km long, circular tunnel and a dozen surface sites. It will initially host an electron-positron particle collider. With an energy frontier hadron collider as a second step, it can serve a world-wide community through the end of the 21st century. This project will validate the key performance enablers at particle accelerators.

FCC-ee: efficient Higgs/electroweak factory

High efficiency Klystron design for FCC-ee

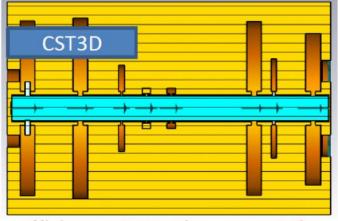

0.8GHz,133.9kV×12.5A×80%>1.3MW

Jinchi Cai & Graeme Burt

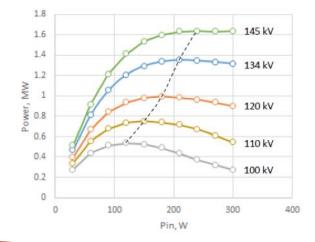

The klystron efficiency impact on the FCC power consumption. Example of the efficiency upgrade from 60% to 80%.

	Klystron eff. 60%	Klystron eff. 80%	Difference
RF power needed for 3TeV CLIC		105 MW	
DC input power	150 MW	123 MW	-27MW
Waste heat	45 MW	18 MW	-27MW
Annual consumption (5500 h assumed)	825 GWh	676 GWh	-149 GWh
Annual cost (60 CHF/MWh assumed)	49.5 MCHF	40.5 MCHF	-9 MCHF

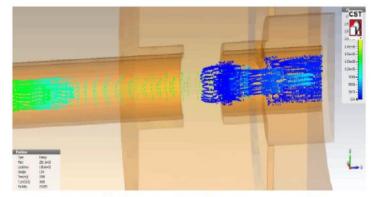

- FCC requires 105 MW of RF power, but the DC power is much higher due to limited efficiency
- Increasing the efficiency by just 20% would save CERN 9 MCHF / year by saving 149 GWh of electricity
- CERN and Lancaster are investigating new methods of increasing klystron efficiency

Efficiency=79%, Time cost=50h

 $B_z = 0.07T (5xBr)$. Efficiency **79**%

FCC-hh: big step in performance

order of magnitude performance increase in energy & luminosity

100 TeV cm collision energy (vs 14 TeV for LHC)

20 ab⁻¹ per experiment collected over 25 years of operation (vs 3 ab⁻¹ for LHC)

similar performance increase as from Tevatron to LHC

key technology: high-field magnets

FCChh: High-Field Magnets

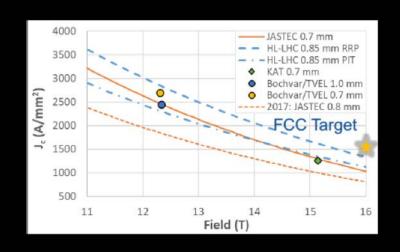

Worldwide FCC Nb₃Sn program

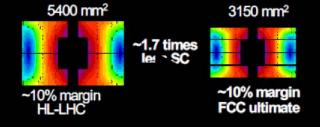

Main development goal is wire performance increase:

- J_c (16T, 4.2K) > 1500 A/mm² →50% increase wrt HL-LHC wire
- Reduction of coil & magnet cross-section

After only one year of development, prototype Nb3Sn wires from several new industrial FCC partners already achieve HL-LHC performance

Conductor activities for FCC started in 2017:

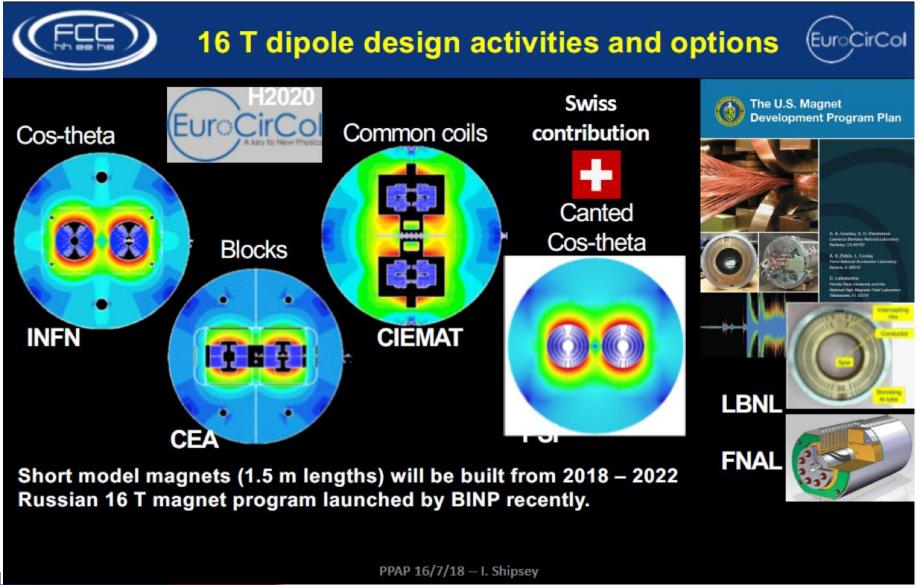

- · Bochvar Institute (production at TVEL), Russia
- KEK (Jastec and Furukawa), Japan
- KAT, Korea
- Columbus, Italy
- University of Geneva, Switzerland
- Technical University of Vienna, Austria
- SPIN, Italy
- University of Freiberg, Germany
 In addition, agreements under preparation:
- Bruker, Germany
- Luvata Pori, Finland

PPAP 16/7/18 -- I. Shipsey

FCChh: High-Field Magnets

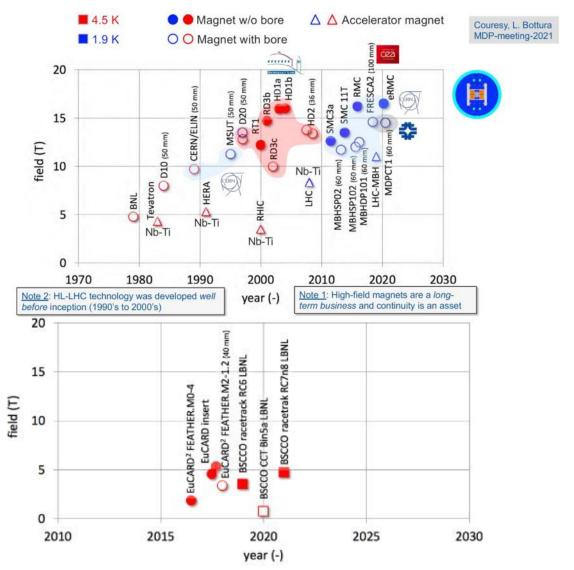

High-Field Magnets latest: Pierre Vedrine, on behalf of HFM Expert Panel High-Field Magnet R&D Status, 9 July 2021

- ► High Field Magnets (HFM) are among the key technologies that will enable the search for new physics at the energy frontier.
- ► Approved projects (HL-LHC) and studies for future circular machines (FCC, SppC) call for the development of superconducting magnets that produce fields beyond those attained in the LHC.
- ▶ Progress in highest field attained in European and international programs (EU-FP6 CARE, EU-FP7 EuCARD, EuCARD2, HL-LHC, ARIES, on-going I-FAST, HFM & US-DOE programs)

High-Field Magnets latest:

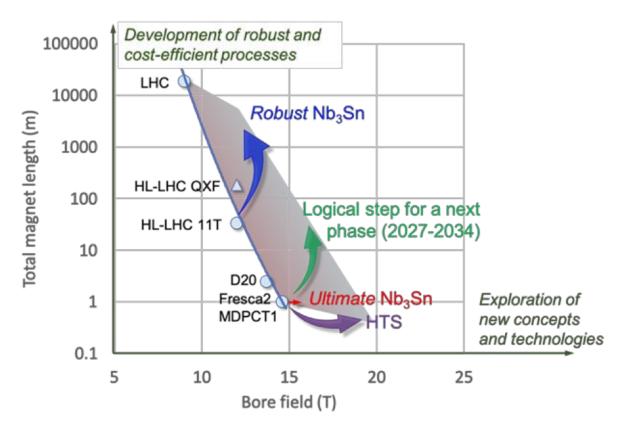

Pierre Vedrine, on behalf of HFM Expert Panel

High Field Magnet R&D Status, 9 July 2021

GOALS OF A HIGH FIELD MAGNETS R&D PROGRAM

- ▶ Demonstrate Nb₃Sn magnet technology for large scale deployment, pushing it to its practical limits, both in terms of maximum performance as well as production scale
 - Demonstrate Nb₃Sn full potential in terms of ultimate performance (target 16 T)
 - Develop Nb₃Sn magnet technology for collider-scale production, through robust design, industrial manufacturing processes and cost reduction (benchmark 12 T)
- ▶ Demonstrate suitability of HTS for accelerator magnet applications, providing a proof-of-principle of HTS magnet technology beyond the reach of Nb₃Sn (target in excess of 20 T)
- ► Implemented as a <u>focused, innovative, mission-style</u>
 R&D of collaborative nature

FUTURE CIRCULAR FCC CDR and Study Documentation

FCC Feasibility Study

Main deliverables and milestones (i):

Physics, experiments and detectors

- ☐ consolidation of physics case for full FCC programme;
- ☐ requirements on theoretical calculations, Monte Carlo generators and oth
- ☐ detector concepts for FCC-ee and FCC-hh (also based on experience with F
- □ detector design and R&D (synergies with "R&D for future detectors" at CERN :
- ☐ requirements on accelerator performance, technical infrastructure, compu

Accelerators

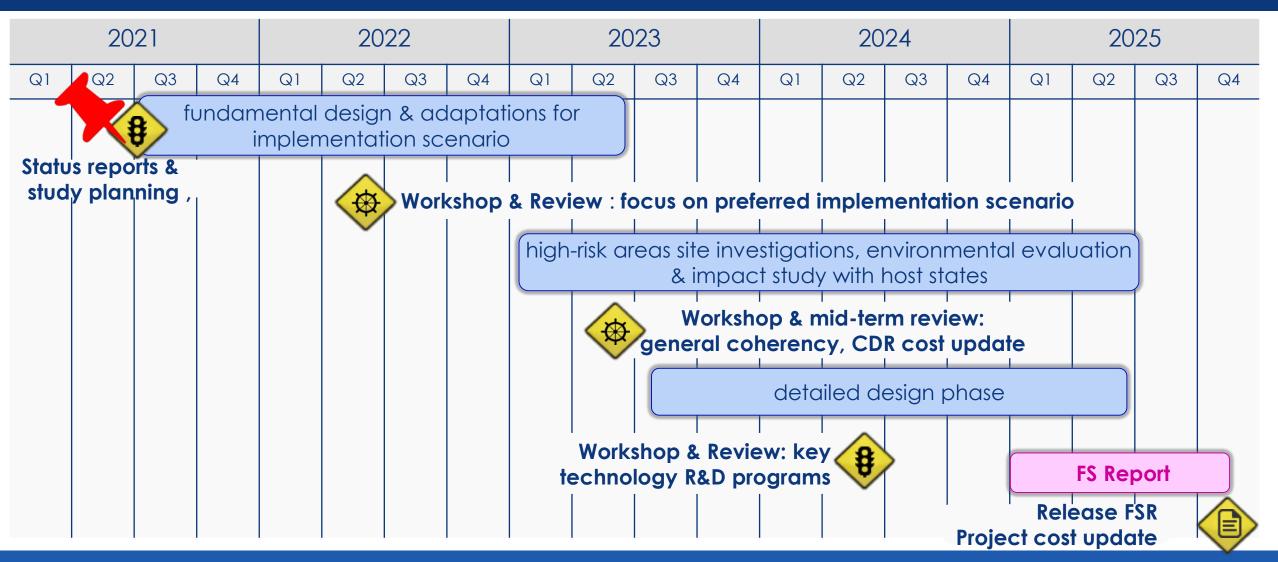

- ☐ design of FCC-ee and FCC-hh, and their injectors;
- □ development of key technologies for both colliders, including high-field su SCRF, high-efficiency power production, and other sustainable and environtechnologies; milestones will be finalised once Accelerator R&D roadmap
- □ machine-detector interface for FCC-ee (final focus magnets and compensation solenoids)

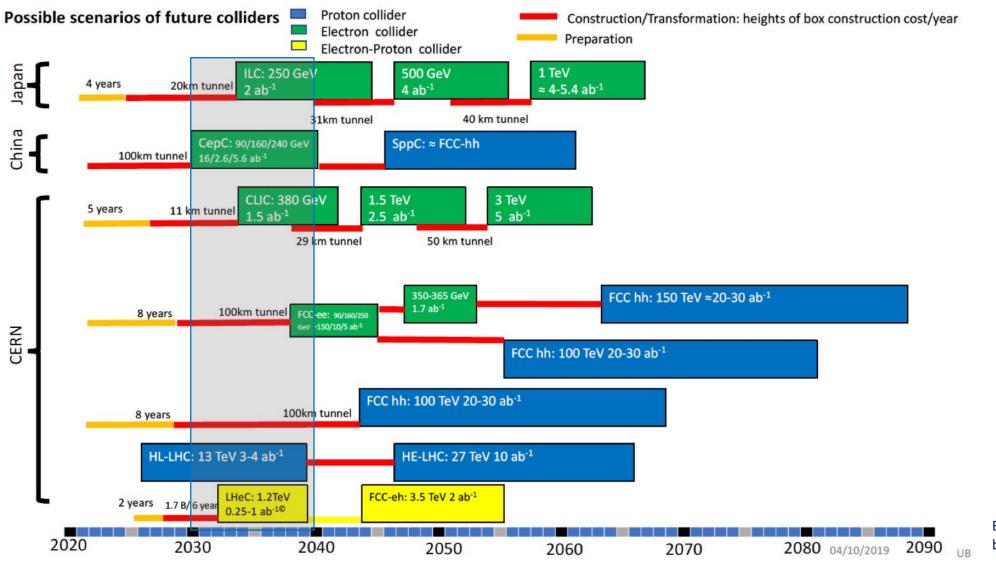

Feasibility study timeline

Timeline of Future Colliders

Possible scenarios

Higgs factory – which flavour?

Muon collider?

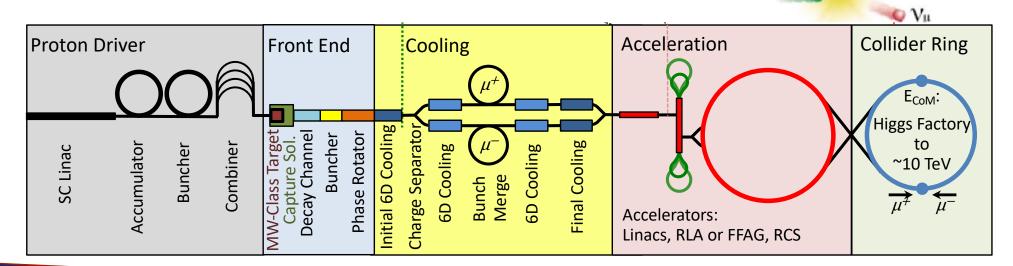

Lenny Rivkin

Muon Collider: protons on target

- Main advantage of $\mu^+\mu^-$ compared to e⁺e⁻ is higher mass: (0.115 MeV / 105.658 MeV) ⁴ less synchrotron radiation
 - TeV collider fits in small ring!

Challenges:

- Muon lifetime is only 2.197 μs.
 - Need to rapidly accelerate muons to relativistic energies, so lifetime in lab frame is extended.
- Muons created by protons on target & pion decay.

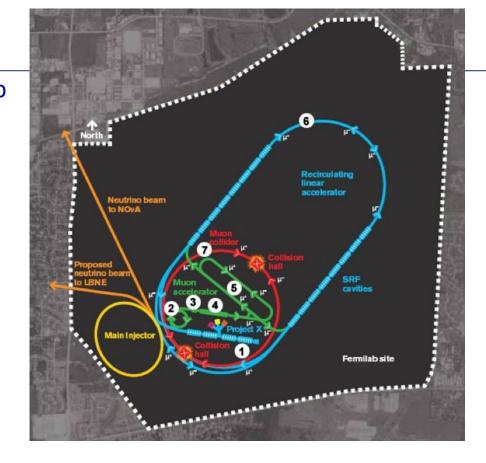

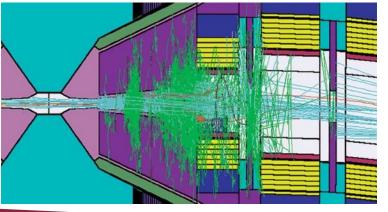

Muon Collider

- 4 TeV muon collider would fit on the former Tevatron site at Fermilab
- A muon collider in the LHC tunnel could reach 14TeV CoM

Main technical challenges:

- Muon beam from target is produced with extremely large emittance:
 - Need rapid cooling so short-lived muons can be captured (see next slides)
- Beam quality, cost and power
- Machine Detector Interface:
 - After acceleration, the muon beam decay products interact with the machine components tens of meters from the Interaction Point (IP), generating high fluxes of beam induced background (BIB) on the detector.

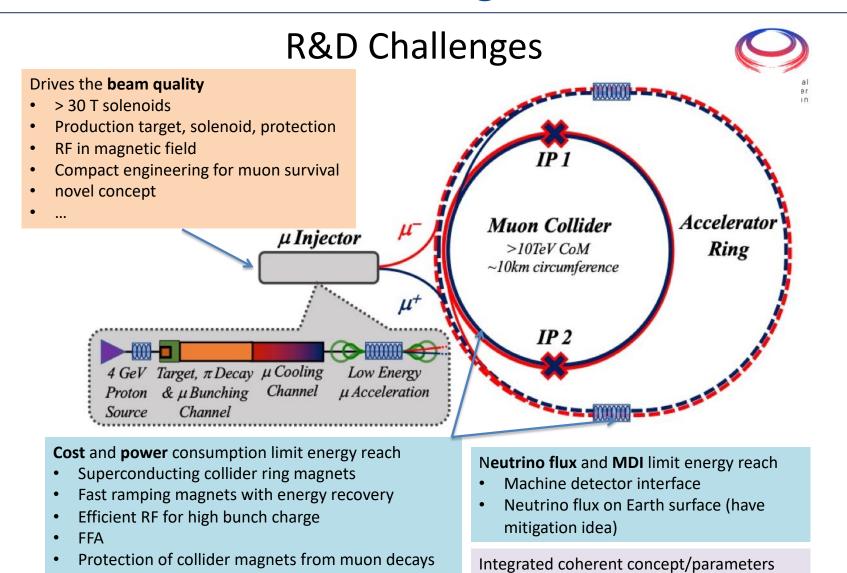

N Mokhov

Muon Collider

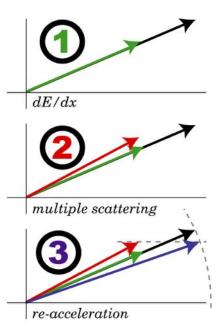

Muons Progress

MICE experiment: cool demonstration

- High intensity protons on target generate pions that decay:
 - Large 6D emittance beams must be cooled:
 - Muon ionization cooling demonstration by MICE.

Instrumentation $\frac{d\varepsilon_{T}}{dz} \approx -\frac{\varepsilon_{T}}{E_{\mu}\beta^{2}} \frac{dE_{\mu}}{dz} + \frac{\beta_{\perp}}{2mc^{2}\beta^{3}} \frac{(13.6 \text{ m})}{E_{\mu}}$

Demonstration of cooling by the Muon Ionization Cooling Experiment

https://www.nature.com/articles/s41586-020-1958-9

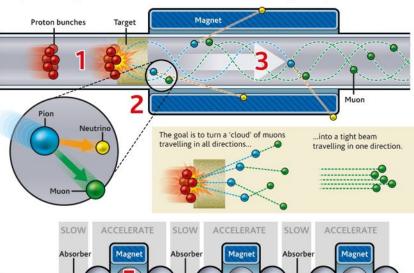

MICE Muon Ionization Cooling Experiment

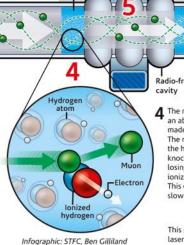

MICE has made the first ever demonstration of the ionization cooling of muons

– a major step in the journey to create the world's most powerful particle accelerator.

1 Bunches of protons are accelerated into a target of dense material (such as tungsten or mercury). The atoms within the target emit a particle called a pion.

Pions are unstable and they quickly decay into a muon and a neutrino. 3 The neutrinos, being virtually massless and without charge, pass out of the experiment. Magnets direct charged muons of the correct energy moving in the right direction.

The muons pass through an absorber material made of liquid hydrogen. The muons collide with the hydrogen atoms and knock off electrons, losing energy to this ionization of the atoms. This causes the muons to slow down.

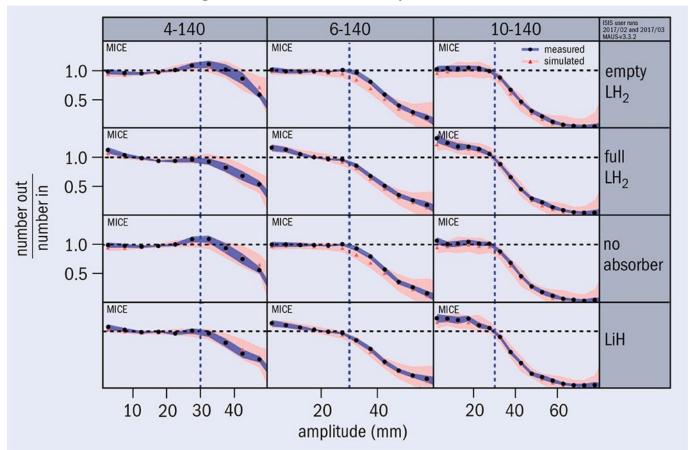

5 Magnetic fields guide the particles into radio-frequency cavities. These cavities contain electromagnetic fields that give the muons back their lost energy by replacing the momentum lost in the direction of the beam. In this way, the muons lose energy and momentum in all directions and are accelerated in only one direction.

This process is repeated until the muon beam is almost laser-like, ready for injection into the main accelerator.

MUON

MICE experiment: cool demonstration

- High intensity protons on target generate pions that decay:
 - Large 6D emittance beams must be cooled:
 - Muon ionization cooling demonstration by MICE.

A ratio of greater than unity is observed with both the full LH2 absorber and the LiH absorber

https://www.nature.com/articles/s41586-020-1958-9

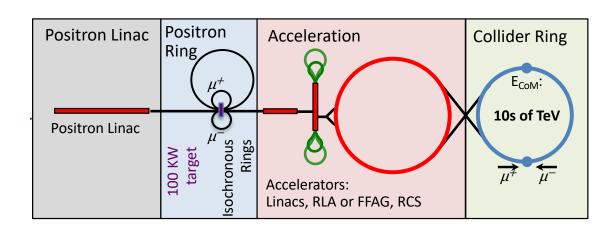

Muon collider alternative schemes

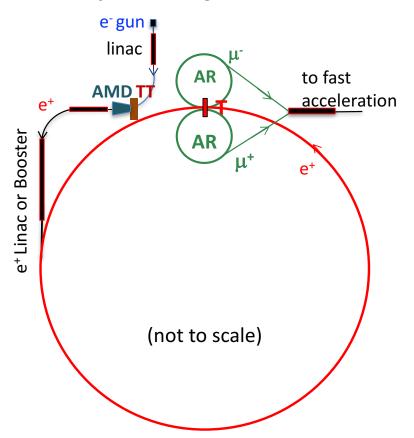

LEMMA: Low Emittance Muon Accelerator

• High intensity 45 GeV e+ beam hits thin target (0.01 rad length) collides with e- in target, giving muon pair just above threshold:

• Small emittance and small energy spread, therefore no need for cooling.

6.2 km storage ring.

Muon collider alternative schemes

Very Recent Concept

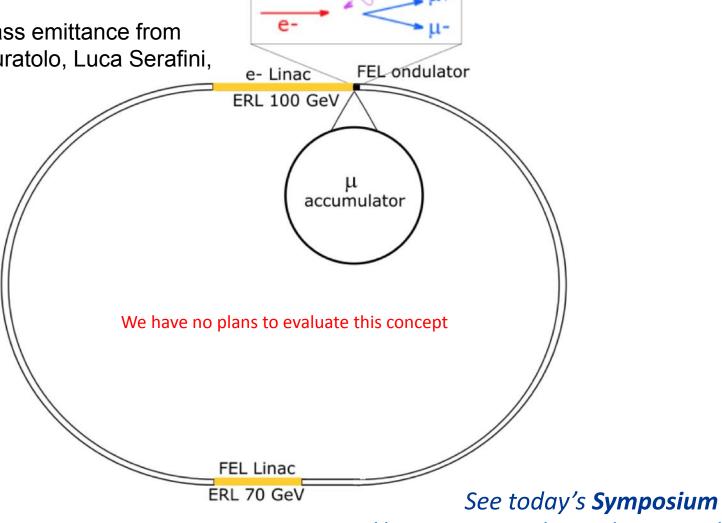

"GeV muon beams with picometer-class emittance from electron-photon collisions" Camilla Curatolo, Luca Serafini,

https://arxiv.org/abs/2106.03255

 Concept of a 100 GeV eERL with X-Ray FEL as basis for a muon collider

- Muons are produced via the
 e− + γ → e− + μ+/μ− reaction
- The calculated geometric emittance is 10 picometer-radian
- Since only a small number of interactions occur, the energy of the electron beam is recovered in an ERL configuration

Table top accelerators?

How to increase acceleration gradient beyond conventional RF 100 MV/m (CLIC

technology)?

RF Acceleration: scaling with frequency

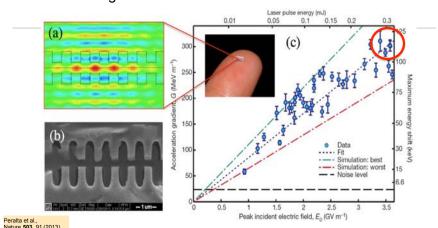

Laser dielectric / THz

Dielectric Laser Accelerators

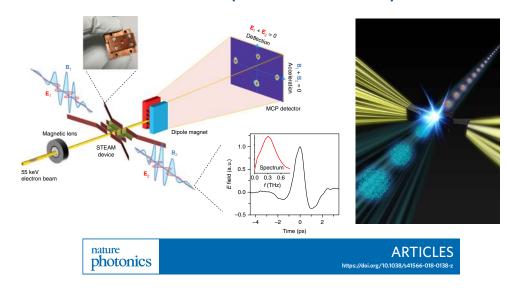

- High electric field at optical wavelengths:
- Gradients < 0.3-1 GeV/m</p>
- Staging rather inefficient, lowers average gradient
- Laser efficiency -> high power requirements.

Peak gradient as a function of Laser Field

THz structures

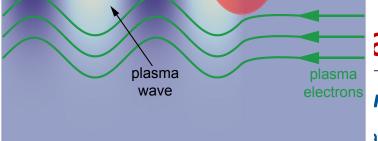

- Easier to manufacture / control at THz wavelength.
- Recent demonstration of THz accelerated beams (>30 keV so far):

Segmented terahertz electron accelerator and manipulator (STEAM)

Dongfang Zhang 0,2,5* , Arya Fallahi 0,15 , Michael Hemmer 0 , Xiaojun Wu^{1,4}, Moein Fakhari ^{1,2}, Yi Hua¹, Huseyin Cankaya¹, Anne-Laure Calendron¹², Luis E. Zapata¹, Nicholas H. Matlis¹ and Franz X. Kärtner 0,12,3

Moon beams?

A very high energy hadron collider on the Moon

James Beacham^{1,*} and Frank Zimmermann^{2,†}

¹Duke University, Durham, N.C., United States

²CERN, Meyrin, Switzerland

(Dated: June 17, 2021)

The long-term prospect of building a hadron collider around the circumference of a great circle of the Moon is sketched. A Circular Collider on the Moon (CCM) of $\sim 11000~\rm km$ in circumference could reach a proton-proton center-of-mass collision energy of 14 PeV — a thousand times higher than the Large Hadron Collider at CERN — optimistically assuming a dipole magnetic field of 20 T. Siting and construction considerations are presented. Machine parameters, powering, and vacuum needs are explored. An injection scheme is delineated. Other unknowns are set down. Through partnerships between public and private organizations interested in establishing a permanent Moon presence, a CCM could be the (next-to-next-generation discovery machine and a natural successor to next-generation machines, such as the proposed Future Circular Collider at CERN or a Super Proton-Proton Collider in China, and other future machines, such as a Collider in the Sea, in the Gulf of Mexico. A CCM would serve as an important stepping stone towards a Planck-scale collider sited in our Solar System.

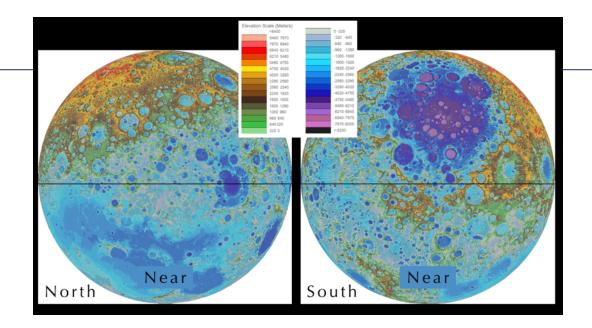

FIG. 2. Schematic possible trajectory (black line) of a Circular Collider on the Moon (CCM) that could potentially avoid several major elevation changes, though not all. In the left image the north pole of the Moon is centered, while in the right image the south pole is centered. Images modified from Ref. [31]; the originals were constructed with data collected by the Lunar Reconnaissance Orbiter [32–36].

Parameter	CCM	FCC-hh	HL-LHC
Max. beam energy E_{beam} [TeV]	7,000	50	7
Circumference C [km]	11,000	97.8	26.7
Arc dipole magnet field B_{dip} [T]	20	16	8.3
Luminosity / IP L [10^{34} cm $^{-2}$ s $^{-1}$]	~20,000	~30	5 (leveled)
Number of events/crossing (pile-up)	$\sim 10^{6}$	~1000	135
Max. integrated lum./experiment [ab ⁻¹ /y]	~2000	1.0	0.35

TABLE I. Tentative proton-proton parameters for CCM, compared with FCC-hh and HL-LHC [40].

Summary

- Technology developments for HL-LHC are applicable at future lepton and hadron colliders:
 - Novel collimation, SCRF, crab-cavities, diagnostics, cold powering, laser of engineering surfaces...
- The EU strategy update has helped to launch several feasibility studies, especially towards finding the near term technical solutions to create a Higgs Factory.
- Much progress has been made and further innovation is needed to address challenges across 5 technology pillars for future machines:
 - High-field magnets; High-gradient plasma/laser, high-gradient RF structures; muon beams, ERLs.
 - Community feedback is welcome to the Accelerator Roadmap: https://indico.cern.ch/event/1053889/

Thanks to the YETI21 organisers and all who contributed slides!
