“I know one thing, that I know nothing.”

–Socrates

- Gravitational interactions.
- Mostly electrically neutral.
- Stable or very slow decay rate.
- Non-Baryonic.
- Cold/Warm and non-relativistic today.

The axion (like) particle

Notably, the original axion was originally introduced in order to solve the *strong-CP problem* of the SM. Axion-like-particles (ALPs) arise in a number of new physics models, beyond the SM.

Axions and ALPs generally:

- Have suppressed interactions with photons.
- Are (mostly) stable.
- Non-baryonic by definition.
- Light but non-relativistic around the epoch of structure formation.

6

Outlook

Axions and ALPs follow a similar equation of motion (EOM):

$$\left(\frac{d^2}{dt^2} + 3H(t) \frac{d}{dt} \right) \theta(t) + \tilde{m}_a^2(t) \sin \theta(t) = 0 ,$$

where $\theta = A/f_a$, with A the axion field, and f_a some energy scale that characterises the potential (Peccei-Quinn breaking scale).

Hard (in general).

The classical analogue is the damped pendulum with time-dependent length and friction:

- There is no closed form solution.
- There are no constants of motion during its entire evolution.
- No package/library/program available!

Hard (in general).

The classical analogue is the damped pendulum with time-dependent length and friction:

- There is no closed form solution.
- There are no constants of motion during its entire evolution.
- No package/library/program available!

MiMeS *simulates the evolution of the axion/ALP, for (virtually) any cosmological scenario and axion/ALP (thermal) mass.*

Some time at the very early Universe, $\tilde{m}_a \ll H(T)$, with

$$\ddot{\theta} + 3H \dot{\theta} \approx 0 .$$

The solution is

$$\theta = \theta_{\text{ini}} + C \int_0^t dt' \left(\frac{a(t' = 0)}{a(t')} \right)^3 .$$

So, $\dot{\theta} \sim a^{-3}$. Since we are interested in θ once the potential becomes relevant (*i.e.* much later times), $\dot{\theta} \approx 0$.¹ Therefore, we can begin integration at some point with $3H \gg \tilde{m}_a$, and set $\theta(t = t_{\text{ini}}) = \theta_{\text{ini}}$ and $\dot{\theta}(t = t_{\text{ini}}) = 0$.

¹ Extensions of this are the “Kinetic misalignment mechanism” R. T. Co, L. J. Hall and K. Harigaya, *Phys. Rev. Lett.* **124** (2020) no.25, 251802 [arXiv:1910.14152 [hep-ph]], C. F. Chang and Y. Cui, *Phys. Rev. D* **102** (2020) no.1, 015003 [arXiv:1911.11885 [hep-ph]], and “Frictional misalignment” A. Papageorgiou, P. Quilés and K. Schmitz, [arXiv:2206.01129 [hep-ph]].

(Bad) Assumptions

“Even the finest sword plunged into salt water will eventually rust.”

–Sun Tzu

- Assume $\theta \ll 1$, and linearise the EOM. *Not general.*
- Assume that at $\tilde{m}_a(T_{\text{osc}}) \approx 3H(T_{\text{osc}})$ we have $\dot{\theta}(T_{\text{osc}}) = 0$. *Not very precise.*
- For $T < T_{\text{osc}}$ the axion oscillates harmonically. *Not good.*
- Assume that $\theta_{\text{osc}} \approx \theta_{\text{ini}}$. *Generally quite bad.*

(Bad) Assumptions

“Even the finest sword plunged into salt water will eventually rust.”

–Sun Tzu

- Assume $\theta \ll 1$, and linearise the EOM. *Not general.*
- Assume that at $\tilde{m}_a(T_{\text{osc}}) \approx 3H(T_{\text{osc}})$ we have $\dot{\theta}(T_{\text{osc}}) = 0$. *Not very precise.*
- For $T < T_{\text{osc}}$ the axion oscillates harmonically. *Not good.*
- Assume that $\theta_{\text{osc}} \approx \theta_{\text{ini}}$. *Generally quite bad.*

These result in “WKB”-approximate solution

$$\theta(t) \approx \theta_{\text{ini}} \left(\frac{3}{4}\right)^{1/4} \sqrt{\frac{\tilde{m}_a(T_{\text{osc}})}{\tilde{m}_a(T)}} \left(\frac{a}{a_{\text{osc}}}\right)^{-3/2} \cos\left(\int_{t_{\text{osc}}}^t dt' \tilde{m}_a(t')\right),$$

which gives us:

$$\rho_{a,0} = \gamma^{-1} \frac{s_0}{s_{\text{osc}}} \frac{1}{2} f_a^2 m_a \tilde{m}_{a,\text{osc}} \theta_{\text{ini}}^2,$$

where γ the amount of entropy injection between T_{osc} and today.

Is it that bad?

Life before MiMeS:

- The approximations can be tested against numerical results in a case-by-case basis. *No measure of accuracy.*
- No available tool that can help us reproduce published results obtained by numerical integration. *Reproducing results means reproducing effort.*
- Simply checking if an ALP model is compatible with a cosmological scenario is *slow* or *inaccurate*.

6

Outlook

We need accurate code that solves the EOM, but most importantly we need *reproducible* results!

- MiMeS is a C++ header-only library that contains various templated classes.
- MiMeS comes with a `python` interface.
- MiMeS is *easy to use*; anyone can run it and see if their model can work or check against the literature.
- MiMeS is reasonably fast; less than 0.05 *s* for the scenarios tested.
- MiMeS provides full access to results and their errors, which can help determine if the results are accurate.
- MiMeS asks the user to decide when to start, stop, and when adiabaticity is reached.

“It is the empty space that makes a bowl useful.”

–Laozi

MiMeS is built as minimally as possible:

- MiMeS relies on `NaBBODES`² and `SimpleSplines`³.
- Guaranteed seamless integration with MiMeS.
- There is always going to be a compatible version of these libraries that works with MiMeS.
- You only need a C++ compiler.⁴

² <https://github.com/dkaramit/NaBBODES>.

³ <https://github.com/dkaramit/SimpleSplines>.

⁴Support of C++17 for full functionality.

Sidenote: adiabatic invariant – J

Given a system with Hamiltonian $\mathcal{H}(\theta, p; t)$, the equations of motion are

$$\dot{p} = -\frac{\partial \mathcal{H}}{\partial \theta}, \quad \dot{\theta} = \frac{\partial \mathcal{H}}{\partial p}.$$

Also,

$$d\mathcal{H} = \dot{\theta} dp - \dot{p} d\theta + \frac{\partial \mathcal{H}}{\partial t} dt.$$

If this system exhibits closed orbits (e.g. if it oscillates), we define

$$J \equiv C \oint p d\theta,$$

where the integral is over a closed path (e.g. a period, T), and C indicates that J can always be rescaled with a constant. If the Hamiltonian varies slowly during a cycle,

$$\frac{dJ}{dt} = C \oint \left(\dot{p} d\theta + p d\dot{\theta} \right) = C \int_t^{t+T} \frac{\partial \mathcal{H}}{\partial t'} dt' \approx 0.$$

So, J is an adiabatic invariant!

Sidenote: adiabatic invariant – II

The Hamiltonian that results in the EOM

$$\mathcal{H} = \frac{1}{2} \frac{p^2}{f_a^2 a^3} + V(\theta) a^3 ,$$

with

$$p = f_a^2 a^3 \dot{\theta} , \quad V(\theta) = \tilde{m}_a^2 f_a^2 (1 - \cos \theta) .$$

If \mathcal{H} varies slowly ($\dot{\tilde{m}}_a(T)/\tilde{m}_a \ll \tilde{m}_a$ and $H \ll \tilde{m}_a$):

$$\begin{aligned} J &= \frac{\oint p d\theta}{\pi f_a^2} = \frac{1}{\pi f_a^2} \oint \sqrt{2(\mathcal{H}(\theta) - V(\theta) a^3) f_a^2 a^3} d\theta \\ &= \frac{2}{\pi f_a^2} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{2(\mathcal{H}(\theta_{\text{peak}}) - V(\theta) a^3) f_a^2 a^3} d\theta \\ &= \frac{2\sqrt{2}}{\pi f_a} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{V(\theta_{\text{peak}}) - V(\theta) a^3} d\theta \\ &= \frac{2\sqrt{2}}{\pi} \tilde{m}_a a^3 \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{\cos \theta - \cos \theta_{\text{peak}}} d\theta , \end{aligned}$$

is the adiabatic invariant – up to a multiplication with a constant.

Sidenote: adiabatic invariant – II

The Hamiltonian that results in the EOM

$$\mathcal{H} = \frac{1}{2} \frac{p^2}{f_a^2 a^3} + V(\theta) a^3 ,$$

with

$$p = f_a^2 a^3 \dot{\theta} , \quad V(\theta) = \tilde{m}_a^2 f_a^2 (1 - \cos \theta) .$$

If \mathcal{H} varies slowly ($\dot{\tilde{m}}_a(T)/\tilde{m}_a \ll \tilde{m}_a$ and $H \ll \tilde{m}_a$):

$$\begin{aligned} J &= \frac{\oint p d\theta}{\pi f_a^2} = \frac{1}{\pi f_a^2} \oint \sqrt{2(\mathcal{H}(\theta) - V(\theta) a^3) f_a^2 a^3} d\theta \\ &= \frac{2}{\pi f_a^2} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{2(\mathcal{H}(\theta_{\text{peak}}) - V(\theta) a^3) f_a^2 a^3} d\theta \\ &= \frac{2\sqrt{2}}{\pi f_a} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{V(\theta_{\text{peak}}) - V(\theta) a^3} d\theta \\ &= \frac{2\sqrt{2}}{\pi} \tilde{m}_a a^3 \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} \sqrt{\cos \theta - \cos \theta_{\text{peak}}} d\theta , \end{aligned}$$

is the adiabatic invariant – up to a multiplication with a constant.

Important: θ_{peak} is the peak of the oscillation.

Using adiabatic invariant

We rewrite the adiabatic invariant as

$$J = a^3 \tilde{m}_a \theta_{\text{peak}}^2 f(\theta_{\text{peak}}) ,$$

with

$$f(\theta_{\text{peak}}) = \frac{2\sqrt{2}}{\pi\theta_{\text{peak}}^2} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} d\theta \sqrt{\cos \theta - \cos \theta_{\text{peak}}} ,$$

the so-called anharmonic factor.

Using adiabatic invariant

We rewrite the adiabatic invariant as

$$J = a^3 \tilde{m}_a \theta_{\text{peak}}^2 f(\theta_{\text{peak}}) ,$$

with

$$f(\theta_{\text{peak}}) = \frac{2\sqrt{2}}{\pi \theta_{\text{peak}}^2} \int_{-\theta_{\text{peak}}}^{\theta_{\text{peak}}} d\theta \sqrt{\cos \theta - \cos \theta_{\text{peak}}} ,$$

the so-called anharmonic factor.

J can be used to determine how θ_{peak} changes with time. By definition, at $\theta = \theta_{\text{peak}}$, $p \sim \dot{\theta} = 0$. This means that we can find $\rho_{a,0}$ on the peak of today's θ , as

$$\rho_{a,0} = \gamma^{-1} \frac{s_0}{s_*} m_a \tilde{m}_{a,*} \frac{1}{2} f_a^2 \theta_{\text{peak},*}^2 f(\theta_{\text{peak},*}) ,$$

where T_* the temperature at which adiabaticity was reached, and γ the entropy injection between T_* and today (*i.e.* $s_0 = \gamma a_*^3 s_*$).

MiMeS solves the transformed EOM: ⁵

$$\frac{d\zeta}{du} + \left[\frac{1}{2} \frac{d \log H^2}{du} + 3 \right] \zeta + \left(\frac{\tilde{m}_a}{H} \right)^2 \sin \theta = 0 .$$
$$\frac{d\theta}{du} - \zeta = 0 .$$

The parameter u is “time” $u \equiv \log(a/a_{\text{ini}})$. ⁶

⁵Suitable for Runge-Kutta.

⁶ With a_{ini} the initial value of the scale factor. It corresponds to T_{ini} .

MiMeS solves the transformed EOM: ⁵

$$\frac{d\zeta}{du} + \left[\frac{1}{2} \frac{d \log H^2}{du} + 3 \right] \zeta + \left(\frac{\tilde{m}_a}{H} \right)^2 \sin \theta = 0 .$$
$$\frac{d\theta}{du} - \zeta = 0 .$$

The parameter u is “time” $u \equiv \log (a/a_{\text{ini}})$. ⁶

- Integration starts at T_{ini} such that $3H(T_{\text{ini}})/m_a(T_{\text{ini}}) = x \gg 1$, with a user defined x (T_{ini} is automatically determined).
- Initial conditions, set at T_{ini} , $\zeta(T_{\text{ini}}) = 0$ and $\theta(T_{\text{ini}}) = \theta_{\text{ini}}$. The initial angle θ_{ini} is user defined.
- MiMeS stops integrating when J becomes slowly varying over enough cycles. This is a user defined condition.

⁵Suitable for Runge-Kutta.

⁶ With a_{ini} the initial value of the scale factor. It corresponds to T_{ini} .

6

Outlook

There are several ways you can get a stable version of MiMeS:

1

`git clone -b stable https://github.com/dkaramit/MiMeS.git`.
This is the preferred way, as it is guaranteed to be the latest stable version.

2

Go to mimes.hepforge.org/downloads, and download it.

3

Go to github.com/dkaramit/MiMeS/releases, and download a released version.

You can get the most up-to-date code – not always the most stable one – including the latest version of NaBBODES and SimpleSplines, by running

```
1  git clone https://github.com/dkaramit/MiMeS.git
2  cd MiMeS
3  git submodule init
4  git submodule update --remote
```

Configure (and make)

There is no need to install anything if you are going to use MiMeS in a C++ program. The only thing you *must* do is run

```
1 bash configure.sh
```

Alter that, you can include the header file `MiMeS/MiMeS.hpp`, and you are good to go.

However, you can also run

- `make lib`, in order to produce the (shared) libraries. This is needed in order to run the `python` interface.
- `make examples`, in order to compile the examples in `MiMeS/UserSpace/Cpp`.
- `make exec`, in order to produce some test executables (in `MiMeS/exec`). You just need to run them in order to see if you get any segfaults.

There are three classes useful to the user.⁷

⁷ There are various arguments that need to be passed to the constructors, and they are all listed and explained in the Appendix of the documentation.

Template arguments

You need to choose what numeric type to use. This is done by the template argument `LD` which should be `double` (fast) or `long double` (accurate).¹⁰

You also need to tell `MiMeS` which integration strategy to use. This is done by choosing template arguments:

- `Solver` can be set to `1` for Rosenbrock (semi-implicit Runge-Kutta). The `Method` argument in this case can be:
 - `RODASPR2<LD>` (4th order).
 - `ROS34PW2<LD>` (3rd order).
 - `ROS3W<LD>` (2rd order, *very bad*).
- `Solver` can be set to `2` for explicit RK. The `Method` argument can be:
 - `DormandPrince<LD>` (7th order)
 - `CashKarpRK45<LD>` (5th order, *very bad*).
 - `RK45<LD>` (5th order, *very bad*).

¹⁰ You could choose `float`, but we live in 2022.

In order to call the `python` interface of MiMeS, we need to first call `make lib` in the root directory of MiMeS.

Before that, we can take some time to decide what the template arguments and compilation options should be. In the file `MiMeS/Definitions.mk`, you can change the variables:

- `LONGpy=long` will compile the library with `long double` numeric types. `LONGpy=` will compile the library with `double` numeric types.
- `SOLVER` and `METHOD`, as in the template arguments.

Also, in the same file, you can change compilation options:

- **Compiler:**
 - `CC=g++` in order to use the GNU C++ compiler.
 - `CC=clang -lstdc++` in order to use the `clang` C++ compiler.
- **Optimization level:**
 - `OPT=O0`: No optimization.
 - `O=O1, O2, or O3`: all these perform mostly the same (read the compiler documentation for more information on the optimization).
 - `OPT=Ofast`: full optimization (fast, but dangerous).

Assumptions

MiMeS is designed to make as few assumptions as possible.
However, it still assumes that:

MiMeS is designed to make as few assumptions as possible. However, it still assumes that:

- 1 H/\tilde{m}_a increases monotonically with the temperature.

MiMeS is designed to make as few assumptions as possible. However, it still assumes that:

Apart from θ_{ini} and f_a , keep in mind that MiMeS needs:

- 1 The mass of the axion/ALP. A data file or an actual function.
- 2 Data file with $\log a/a_i$ (a_i is some arbitrary value; MiMeS rescales it appropriately), T , and $\log H$ of the underlying cosmology.

What MiMeS expects from you

Apart from θ_{ini} and f_a , keep in mind that MiMeS needs:

- 1 The mass of the axion/ALP. A data file or an actual function.
- 2 Data file with $\log a/a_i$ (a_i is some arbitrary value; MiMeS rescales it appropriately), T , and $\log H$ of the underlying cosmology.
- 3 Value for $3H/\tilde{m}_a \gg 1$, which defines the point where integration begins.

What MiMeS expects from you

Apart from θ_{ini} and f_a , keep in mind that MiMeS needs:

- 1 The mass of the axion/ALP. A data file or an actual function.
- 2 Data file with $\log a/a_i$ (a_i is some arbitrary value; MiMeS rescales it appropriately), T , and $\log H$ of the underlying cosmology.
- 3 Value for $3H/\tilde{m}_a \gg 1$, which defines the point where integration begins.
- 4 Relative difference of J between a given number of peaks at which we consider adiabaticity to have been reached.

What MiMeS expects from you

Apart from θ_{ini} and f_a , keep in mind that MiMeS needs:

- 1 The mass of the axion/ALP. A data file or an actual function.
- 2 Data file with $\log a/a_i$ (a_i is some arbitrary value; MiMeS rescales it appropriately), T , and $\log H$ of the underlying cosmology.
- 3 Value for $3H/\tilde{m}_a \gg 1$, which defines the point where integration begins.
- 4 Relative difference of J between a given number of peaks at which we consider adiabaticity to have been reached.
- 5 Other input, such as the temperature at which integration exits.

Outlook

What we saw:

- MiMeS solves the axion/ALP EOM.
- MiMeS treats both the mass and the underlying cosmology as user inputs.
- MiMeS allows the user to change a number of other things, from the plasma RDOFs to the convergence conditions.

MiMeS **may be amended in the future because:**

- MiMeS should allow the user to consider other flavours of missalignment.
- MiMeS should be able to handle non-vanishing RHS; *i.e.* solve the "driven" dumped time-dependent pendulum.
- MiMeS should be able to compare against searches on the fly.

Thank you!

Breakdown of MiMeS:

Language	files	comment	code
C/C++ Header	35	444	1595
C++	20	198	1106
Python	22	367	1000
SUM:	77	1009	3701

Backup

(equations, derivations, tables)

$$\left(\frac{d^2}{dt^2} + 3H(t) \frac{d}{dt} + \tilde{m}_a^2(t) \right) \theta(t) = 0 .$$

Reparametrize by introducing

$$\theta_{\text{trial}} = \exp \left[i \int dt \left(\psi(t) + 3/2 i H(t) \right) \right] .$$

The Eome, then becomes just

$$\psi^2 = \Omega^2 + i \dot{\psi} ,$$

with $\Omega^2 = \tilde{m}_a^2 - \frac{9}{4}H^2 - \frac{3}{2}\dot{H}$. The solution takes the form

$\psi = \pm \sqrt{\Omega^2 + i\dot{\psi}}$. However, for $\dot{\psi} \ll \Omega^2$ and $\dot{\Omega} \ll \Omega^2$, it can be approximated as

$$\psi \approx \pm \Omega + \frac{i}{2} \frac{d \log \Omega}{dt} .$$

So, after applying the initial conditions, the EOM is solved by

$$\theta(t) \approx \theta_{\text{ini}} \sqrt{\frac{\Omega_{\text{ini}}}{\Omega(t)}} \left(\frac{a}{a_{\text{ini}}}\right)^{-3/2} \cos\left(\int_{t_{\text{ini}}}^t dt' \Omega(t')\right).$$

Taking $t_{\text{ini}} = t_{\text{osc}}$ (*i.e.* $\dot{\theta}(t_{\text{osc}}) = 0$, which is not generally good), have

$$\theta(t) \approx \theta_{\text{osc}} \left(\frac{3}{4}\right)^{1/4} \sqrt{\frac{\tilde{m}_a|_{t=t_{\text{osc}}}}{\tilde{m}_a(t)}} \left(\frac{a}{a_{\text{osc}}}\right)^{-3/2} \cos\left(\int_{t_{\text{osc}}}^t dt' \tilde{m}_a(t')\right),$$

where $\theta_{\text{osc}} = \theta|_{t=t_{\text{osc}}}$. This equation is further simplified if we assume that $\theta_{\text{osc}} \approx \theta_{\text{ini}}$ (again not really good), *i.e.*

$$\theta(t) \approx \theta_{\text{ini}} \left(\frac{3}{4}\right)^{1/4} \sqrt{\frac{\tilde{m}_a|_{t=t_{\text{osc}}}}{\tilde{m}_a(t)}} \left(\frac{a}{a_{\text{osc}}}\right)^{-3/2} \cos\left(\int_{t_{\text{osc}}}^t dt' \tilde{m}_a(t')\right).$$

C++ Input

AxionMass class – Definition via file

In order to define an instance of the `AxionMass` class that interpolates the \tilde{m}_a , use the constructor:

```
1 template<class LD>  
2 mimes::AxionMass<LD>(std::string chi_PATH, LD minT=0, LD maxT=mimes::Cosmo::mP)
```

The arguments are:

- 1 `chi_Path`: Relative or absolute path to data file with T (in GeV), $\chi(T)$ (in GeV^4).
- 2 `minT, maxT`: Interpolation limits. These are used in order to stop the interpolation at the closest temperatures that exist in the data file. This means that the actual interpolation limits are $T_{\min} \geq \text{minT}$ and $T_{\max} \leq \text{maxT}$. Beyond these limits the axion mass is assumed to be constant.

The definition of \tilde{m}_a^2 beyond T_{\min} and T_{\max} can be changed to realistic function, using `mimes::AxionMass<LD>::set_ma2_MIN(std::function<LD(LD,LD)> ma2_MIN)` and `mimes::AxionMass<LD>::set_ma2_MAX(std::function<LD(LD,LD)> ma2_MAX)`. These definitions may need the actual values of $T_{\min, \max}$ and $\chi(T_{\min, \max})$. These are obtained from

- `template<class LD> LD mimes::AxionMass<LD>::getTMin()`: This function returns the minimum interpolation temperature, T_{\min} .
- `template<class LD> LD mimes::AxionMass<LD>::getTMax()`: This function returns the maximum interpolation temperature, T_{\max} .
- `template<class LD> LD mimes::AxionMass<LD>::getChiMin()`: This function returns $\chi(T_{\min})$.
- `template<class LD> LD mimes::AxionMass<LD>::getChiMax()`: This function returns $\chi(T_{\max})$.

Note that all `std::function<LD(LD,LD)>` can be any callable object that takes T and f_a and returns \tilde{m}_a^2 .

AxionMass class – Definition via function

In order to define an instance of the `AxionMass` class via a function, use the constructor:

```
1 template<class LD>  
2 mimes::AxionMass<LD>(std::function<LD(LD,LD)> ma2)
```

Here, `ma2` can be any callable object that takes T and f_a and returns \tilde{m}_a^2 .

Axion class – Expected input

The constructor of the `Axion` class is

```
1 template<class LD, const int Solver, class Method>
2 mimes::Axion<LD, Solver, Method>(LD theta_i, LD fa, LD umax, LD TSTOP,
3     LD ratio_ini, unsigned int N_convergence_max, LD convergence_lim,
4     std::string inputFile, AxionMass<LD> *axionMass, LD initial_step_size=1e-2,
5     LD minimum_step_size=1e-8, LD maximum_step_size=1e-2,
6     LD absolute_tolerance=1e-8, LD relative_tolerance=1e-8, LD beta=0.9,
7     LD fac_max=1.2, LD fac_min=0.8, unsigned int maximum_No_steps=10000000)
```

The input that `MiMeS` expects is:

- 1 `theta_i`: Initial angle.
- 2 `fa` The PQ scale.
- 3 `umax`: Once $u = \log a/a_i > umax$, the integration stops. Typical value: ~ 500 .
- 4 `TSTOP`: Once $T < TSTOP$, integration stops. Typical value: 10^{-4} GeV.
- 5 `ratio_ini`: Integration starts at u with $3H/\tilde{m}_a \approx ratio_ini$. Typical value: $\sim 10^3$.
- 6 `N_convergence_max`, `convergence_lim`: Integration stops when the relative difference between two consecutive peaks is less than `convergence_lim` for `N_convergence_max` consecutive peaks.
- 7 `inputFile`: Relative (or absolute) path to a file that describes the cosmology. The columns should be: u T [GeV] $\log H$, with acceding u . Entropy injection should have stopped before the lowest temperature of given in `inputFile`.
- 8 `axionMass`: Instance of `mimes::AxionMass<LD>` class. In C++ this instance is passed as a pointer to the constructor of the `mimes::Axion<LD, Solver, Method>` class, while in python it is simply passed as a variable.

Axion class – Optional input

The optional input, relative to the RK algorithm, is:

- 1 `initial_stepsize`: Initial step-size of the solver. Default value: 10^{-2} .
- 2 `minimum_stepsize`: Lower limit of the step-size. Default value: 10^{-8} .
- 3 `maximum_stepsize`: Upper limit of the step-size. Default value: 10^{-2} .
- 4 `absolute_tolerance`: Absolute tolerance of the RK solver. Default value: 10^{-8} .
- 5 `relative_tolerance`: Relative tolerance of the RK solver. Default value: 10^{-8} .
- 6 `beta`: Aggressiveness of the adaptation strategy. Default value: 0.9.
- 7 `fac_max, fac_min`: The step-size does not change more than `fac_max` and less than `fac_min` within a trial step. Default values: 1.2 and 0.8, respectively.
- 8 `maximum_No_steps`: If integration needs more than `maximum_No_steps` integration stops. Default value: 10^7 .

python **Input**

AxionMass class – Definition via file

The actual constructor of the `AxionMass` in the `python` interface is `AxionMass(*args)`. However, it is intended to be used in *only* two ways. In order to define an instance of the `AxionMass` class that interpolates the \tilde{m}_a , use the constructor as:

1 `AxionMass(chi_PATH, minT=0, maxT=Cosmo.mP)`

The arguments are the same as in the `C++` case.

The definition of \tilde{m}_a^2 beyond T_{\min} and T_{\max} can be changed using `AxionMass.set_ma2_MIN(ma2_MIN)` and `AxionMass.set_ma2_MAX(ma2_MAX)`. These definitions may need the actual values of $T_{\min, \max}$ and $\chi(T_{\min, \max})$. These are obtained from

- `AxionMass.getTMin()`: This function returns the minimum interpolation temperature, T_{\min} .
- `AxionMass.getTMax()`: This function returns the maximum interpolation temperature, T_{\max} .
- `AxionMass.getChiMin()`: This function returns $\chi(T_{\min})$.
- `AxionMass.getChiMax()`: This function returns $\chi(T_{\max})$.

The difference between the `C++` case is that `ma2` cannot be any callable object; it has to be a regular function that takes T and f_a and returns \tilde{m}_a^2 .

AxionMass class – Definition via function

In order to define an instance of the `AxionMass` class via a function, use the constructor as:

1 `AxionMass`(ma2)

The difference between the C++ case is that `ma2` cannot be any callable object; it has to be a regular function that takes T and f_a and returns \tilde{m}_a^2 .

The constructor of the `Axion` class is

```
1 Axion(theta_i, fa, umax, TSTOP, ratio_ini, N_convergence_max, convergence_lim, inputFile,  
2   axionMass, initial_step_size=1e-2, minimum_step_size=1e-8, maximum_step_size=1e-2,  
3   absolute_tolerance=1e-8, relative_tolerance=1e-8, beta=0.9, fac_max=1.2, fac_min=0.8,  
4   maximum_No_steps=10000000)
```

All the arguments are the same as in the C++ case. The only difference is that the `AxionMass` instance (`axionMass`) is not passed as a pointer, as there is no direct way to do it in `python`. However, the underlying object is the same, as it is converted internally using `ctypes`.

Files and compilation variables

There are some paths to file that the user can provide in order to use different data for the RDOF, anharmonic factor, and χ (optional).

These paths are stored as strings in `MiMeS/src/misc_dir/path.hpp` when `bash configure.sh` is run.

These paths can be changed by changing the following variables in `MiMeS/Paths.mk`:

- `cosmoDat`: Relative path to data file with T (in GeV), h_{eff} , g_{eff} .
- `axMDat`: Relative path to data file with T (in GeV), h_{eff} , g_{eff} . This variable can be omitted if the user intends to define all masses via functions.
- `anFDat`: Relative path to data file with θ_{peak} , $f(\theta_{\text{peak}})$.

It is advisable that if the paths change `bash configure.sh` and `make` should be run.

Template arguments

You need to choose what numeric type to use. This is done by the template argument `LD` which should be `double` (fast) or `long double` (accurate).¹¹

You also need to tell `MiMeS` which integration strategy to use. This is done by choosing template arguments:

- `Solver` can be set to `1` for Rosenbrock (semi-implicit Runge-Kutta). The `Method` argument in this case can be:
 - `RODASPR2<LD>` (4th order).
 - `ROS34PW2<LD>` (3rd order).
 - `ROS3W<LD>` (2rd order, *very bad*).
- `Solver` can be set to `2` for explicit RK. The `Method` argument can be:
 - `DormandPrinceRK45<LD>` (7th order)
 - `CashKarpRK45<LD>` (5th order, *very bad*).
 - `RK45<LD>` (5th order, *very bad*).

¹¹ You could choose `float`, but we live in 2021.

Definitions.mk

In order to call the `python` interface of MiMeS, we need to first call `make lib` in the root directory of MiMeS.

Before that, we can take some time to decide what the template arguments and compilation options should be. In the file `MiMeS/Definitions.mk`, you can change the variables:

- `LONGpy=long` will compile the library with `long double` numeric types. `LONGpy=` will compile the library with `double` numeric types.
- `SOLVER` and `METHOD`, as in the template arguments.

Also, in the same file, you can change compilation options:

- **Compiler:**
 - `CC=g++` in order to use the GNU C++ compiler.
 - `CC=clang -lstdc++` in order to use the clang C++ compiler.
- **Optimization level:**
 - `OPT=O0`: No optimization.
 - `O=O1, O2, or O3`: all these perform mostly the same (read the compiler documentation for more information on the optimization).
 - `OPT=Ofast`: full optimization (fast, but dangerous).
