The deconfinement interface tension in SU(N) gauge theories at large N

Motivation

Surface tension not well measured at large N

- Improving on existing data
- Amplitude of surface fluctuations in determining the interface tension

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Eases the tunneling situation due to absence of barriers

Existing Result

Determination through tunneling probability:

$$P \propto exp[-2\sigma A/T_c]$$

 Requires small enough volume for the tunneling to be non-negligible

σ/T_c³ = −0.104(3) + 0.0138(3)N² (Lucini, Teper, Wenger - 2005)

- $\sigma/T_c^3 = -0.333(9) + 0.118(3)N$ in same publication
- Unable to verify N^2 behaviour in study

Setup

- ▶ Plaquette action: $\beta \sum_{p} \{1 \frac{1}{N} ReTr U_{p}\}$ where $\beta = \frac{2N}{g^{2}}$
- Heat bath + overrelaxation updates
- Simulations with HILA on GPUs
- Elongated system to ensure that the interface is a minimal surface

Plaquette Difference

$$\Delta u_{(N_T=6)} = 0.0009686(24) - 0.00385(11)/N^2$$
$$\Delta u_{(N_T=8)} = 0.0002413(24) - 0.00105(8)/N^2$$

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへで

Advantages

- Computation in polynomial time, enables huge volume simulations
- Surface is easily located, unaffected by probability density distribution
- More suitable for cases of stronger transition
- The use of mixed phase configurations result in absence of tunneling barriers that cause slowdown

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Conclusion

- Traditional method works well with smaller systems and when the transition is not too strong
- Complementary method as larger systems are required to explore the continuum limit
- Lots of smearing required
- Presents as a consistent and reliable method for studying stronger transitions in general
