Applying the Worldvolume Hybrid Monte Carlo method to the (1+2)-dim Hubbard model

Friday, 2 August 2024 15:35 (20 minutes)

The Worldvolume Hybrid Monte Carlo (WV-HMC) method [arXiv:2012.08468] is a low-cost algorithm for solving the sign and the ergodicity problems simultaneously. We apply the WV-HMC method to the (1+2)-dim Hubbard model, which can be regarded as a prototype of QCD at finite density. We investigate the computational scaling and compare the results of observables with those obtained by a non-thimble method using the ALF code.
