- ④ Dark Matter
- ⑤ Summary and Outlook

# The Space of Nonabelian Gauge Theories

Consider  $SU(N_c)$  gauge theories with  $N_f$  fermions:

**Figure:** Gauge theory phase diagram PoS Lattice **2018**, 006 (2019).

- $N_f > \frac{11}{2} N_c$ : Not asymptotically free.
- $\frac{11}{2} N_c > N_f > N_{fc}$ : Asymptotically free, but approaches conformality in IR.
- $N_{fc} > N_f$ : Confinement. Low energy states are colorless composites.
- Can generalize to other gauge groups and scalar matter.

# Near-Conformal Gauge Theories

- Near-conformal gauge theories *confine*.
- But only just. The field content is chosen to ensure that they lie just beneath the boundary of the conformal window.
- There is also evidence for a light scalar composite forming in these gauge theories, unlike in QCD.

# Evidence for a Light Scalar I

**Figure:** Lattice data for the masses of composites SU(3) gauge theories with  $N_f = 2$  fermions in 2-index symmetric rep. From the LatHC collaboration: PoS LATTICE2015 (2016) 219.

# Evidence for a Light Scalar II

**Figure:** Lattice data for the masses of composites in the  $SU(3)$  gauge theory with  $N_f = 8$  fundamental fermions from the LSD collaboration: PRD **110** (2024) 5, 054501

# Dilaton EFT

Reviewed in Universe 9 (2023) 1, 10 with T. Appelquist, M. Piai and  
PRD 94 (2016) 5, 054502 by M. Golterman, Y. Shamir

## Field Content

- i  $N_f^2 - 1$  NGB fields  $\pi^a$   
 $\Sigma = \exp\{2i\pi^a T^a / F_\pi\}$   
 $\langle \Sigma \rangle = \mathbb{1}$
- ii Dilaton field  $\chi$   
 $\langle \chi \rangle = F_d$

## Symmetries

### Chiral Symmetry

$$\begin{aligned} \mathrm{SU}(N_f)_L \times \mathrm{SU}(N_f)_R &\rightarrow \mathrm{SU}(N_f)_V \\ \Sigma &\rightarrow L \Sigma R^\dagger \end{aligned}$$

### Scale Invariance

$$\begin{aligned} \text{Scale} \times \text{Poincaré} &\rightarrow \text{Poincaré} \\ \chi(x) &\rightarrow e^\lambda \chi(e^\lambda x) \end{aligned}$$

# Dilaton EFT

## Leading order Lagrangian

$$\mathcal{L} = \frac{1}{2} (\partial_\mu \chi)^2 + \frac{f_\pi^2}{4} \left( \frac{\chi}{f_d} \right)^2 \text{Tr} \left[ \partial_\mu \Sigma \partial^\mu \Sigma^\dagger \right] + \frac{m B_\pi f_\pi^2}{2} \left( \frac{\chi}{f_d} \right)^y \text{Tr} \left[ \Sigma + \Sigma^\dagger \right] - V_\Delta(\chi). \quad (1)$$

- pNGB terms are similar to those in chiral Lagrangian.
- Dependence on dilaton field  $\chi$  is determined by scale invariance.
- See dilaton EFT of Golterman & Shamir: PRD **94** (2016) 5, 054502.

# Dilaton Potential

$$V_{\Delta} = \frac{m_d^2 \chi^4}{4(4 - \Delta) f_d^2} \left[ 1 - \frac{4}{\Delta} \left( \frac{f_d}{\chi} \right)^{4 - \Delta} \right]. \quad (2)$$

- Potential contains a scale invariant term ( $\sim \chi^4$ ) and a deformation ( $\sim \chi^{\Delta}$ ), which explicitly violates scale invariance. We treat  $\Delta$  as a floating parameter that can take a range of values.

# Dilaton Potential

$$V_{\Delta} = \frac{m_d^2 \chi^4}{4(4 - \Delta)f_d^2} \left[ 1 - \frac{4}{\Delta} \left( \frac{f_d}{\chi} \right)^{4-\Delta} \right]. \quad (2)$$

- Potential contains a scale invariant term ( $\sim \chi^4$ ) and a deformation ( $\sim \chi^{\Delta}$ ), which explicitly violates scale invariance. We treat  $\Delta$  as a floating parameter that can take a range of values.
- This potential has a minimum at  $\chi = f_d$ , and a weak curvature  $m_d^2 \ll (4\pi f_d)^2$ .

# Dilaton Potential

$$V_{\Delta} = \frac{m_d^2 \chi^4}{4(4 - \Delta)f_d^2} \left[ 1 - \frac{4}{\Delta} \left( \frac{f_d}{\chi} \right)^{4-\Delta} \right]. \quad (2)$$

- Potential contains a scale invariant term ( $\sim \chi^4$ ) and a deformation ( $\sim \chi^{\Delta}$ ), which explicitly violates scale invariance. We treat  $\Delta$  as a floating parameter that can take a range of values.
- This potential has a minimum at  $\chi = f_d$ , and a weak curvature  $m_d^2 \ll (4\pi f_d)^2$ .
- Potentials of this form are discussed in e.g: Rattazzi & Zaffaroni JHEP **0104**, 021 (2001), GGS PRL **100** 111802, (2008), CCT PRD **100** 095007 (2019).

# Fit to Lattice Data

for SU(3) gauge theory with  $N_f = 8$  Dirac fermions

**Figure:** Lattice data for  $M_\pi^2$ ,  $M_\sigma^2$ ,  $F_\pi^2$  and  $F_\sigma^2$  from LSD Collab: PRD **110** (2024) 5, 054501. The lattice spacing is denoted by  $a$ .

We also include data for the  $\pi$ - $\pi$  scattering length in the  $l=2$ ,  $\ell=0$  channel from LSD Collab: PRD **105** (2022) 3, 034505

# Result Of Global Fit to dEFT

Presented in LSD Collab: PRD **108** (2023) 9, 9

# Result Of Global Fit to dEFT

Presented in LSD Collab: PRD **108** (2023) 9, 9

Parameter	Value and Uncertainty
$y$	2.091(32)
$aB_\pi$	2.45(13)
$\Delta$	3.06(41)
$a^2 f_\pi^2$	$6.1(3.2) \times 10^{-5}$
$f_\pi^2 / f_d^2$	0.1023(35)
$m_d^2 / f_d^2$	1.94(65)
$\chi^2/\text{dof}$	21.3/19=1.12

**Table:** Central values of fit parameters obtained in a six parameter global fit to LSD data for  $M_{\pi,d}^2$ ,  $F_{\pi,S}^2$  and scattering length.

# Interpretation of $\Delta$

- 1 Strongly coupled over large interval of scales  $\implies$  possibility of large anomalous dimensions. Note our lattice fits showed  $y \approx 2$ .

# Interpretation of $\Delta$

- 1 Strongly coupled over large interval of scales  $\implies$  possibility of large anomalous dimensions. Note our lattice fits showed  $y \approx 2$ .
- 2 Allows for new relevant interactions besides (near marginal) gauge interaction.

# Interpretation of $\Delta$

- 1 Strongly coupled over large interval of scales  $\implies$  possibility of large anomalous dimensions. Note our lattice fits showed  $y \approx 2$ .
- 2 Allows for new relevant interactions besides (near marginal) gauge interaction.
- 3  $\Delta$  should be identified with the engineering plus anomalous dimension of this new relevant operator.

# Composite Dark Matter

PRD **110** (2024) 3, 035013 with T. Appelquist and M. Piai.

I want to talk about a description of DM, in which the DM is a composite particle that forms in a new dark sector gauge theory.

Figure: Dark pion (image: Kavli IPMU).

The dark sector gauge theory interacts feebly with the standard model. Dark matter is a **composite** state, analogous to the **pion** of QCD.

# Why Compositeness?

The standard model has three gauge interactions. A fourth may be out there as a hidden sector.

## Features

- Sizable self interactions can affect small scale structure anomalies.
- Confining phase transition may generate observable grav waves.

Our dark matter will be a thermal relic.

# Our Composite Dark Matter Framework

- Suppose the dark sector is a near-conformal gauge theory, and dark matter is the pNGB.
- The low energy spectrum of these gauge theories have a light scalar. Unlike the pNGB, the light scalar carries no conserved charges and so can decay (slowly) to standard model.
- Nevertheless, the pNGBs can annihilate readily into the scalars, so the **freezeout** of this process can set the relic density of pNGBs.
- We describe these low energy states using **dilaton EFT**.

# Our Composite Dark Matter Framework

- Suppose the dark sector is a near-conformal gauge theory, and dark matter is the pNGB.
- The low energy spectrum of these gauge theories have a light scalar. Unlike the pNGB, the light scalar carries no conserved charges and so can decay (slowly) to standard model.
- Nevertheless, the pNGBs can annihilate readily into the scalars, so the **freezeout** of this process can set the relic density of pNGBs.
- We describe these low energy states using **dilaton EFT**.
- In the following, specialise to  $SU(3)$  gauge theory with  $N_f = 8$  fermions for concreteness.

# Dilaton Self-Interactions

The dilaton field  $\chi$  experiences a net potential of

$$W(\chi) \equiv V(\chi) - \frac{M_\pi^2 F_\pi^2 N_f}{2} \left( \frac{\chi}{F_d} \right)^y. \quad (3)$$

Expand potential around its minimum  $\chi = F_d + \bar{\chi}$ :

$$W(\bar{\chi}) = \text{constant} + \frac{M_d^2}{2} \bar{\chi}^2 + \frac{\gamma}{3!} \frac{M_d^2}{F_d} \bar{\chi}^3 + \dots, \quad (4)$$

where  $\gamma \geq 2$  (from unitarity bound) GGS PRL.100 111802, (2008) and  $\gamma$  cannot be too large for EFT to remain weakly coupled.

The functional form of the dilaton potential will not matter in the following. Only  $M_d$ ,  $F_d$  and  $\gamma$  impact on our study.

# Freezeout

The relic density is set by  $\pi\pi \rightarrow \chi\chi$  annihilations freezing out.

## Boltzmann Equation

$$\frac{\partial n_\pi}{\partial t} + 3Hn_\pi = -\langle\sigma_{2\pi\rightarrow 2\chi}v\rangle n_\pi^2 + \langle\sigma_{2\chi\rightarrow 2\pi}v\rangle (n_\chi^{\text{eq}})^2. \quad (5)$$

We solve numerically to get the relic density of pNGBs today.

We have taken  $\Gamma_{\chi\rightarrow\text{SM}}$  large enough to maintain dilatons in thermal equilibrium with SM so that  $n_\chi = n_\chi^{\text{eq}}(T_{\text{SM}})$ . More details on SM couplings to follow.

# Thermally Averaged Cross Sections

The inverse annihilation process  $\chi\chi \rightarrow \pi\pi$  can happen for zero kinetic energy in the initial state, because  $\Delta > 0$ . We compute its cross section using dilaton EFT:

For  $T \ll M_\pi$ , the thermal averaged x-section  $\approx$  x-section at  $\vec{p} = 0$ :

$$\langle \sigma_{2\chi \rightarrow 2\pi} v \rangle = \frac{M_\pi^2 N_\pi}{36\pi F_d^4} \sqrt{\Delta(2+\Delta)} (1+\Delta)(5+\gamma)^2, \quad (6)$$

where the mass splitting is  $\Delta \equiv (M_d - M_\pi)/M_\pi$ . We take  $0 < \Delta < 1/2$ , as seen in lattice data.

# Forbidden Dark Matter

However, the calculation of the thermal average  $\langle \sigma_{2\pi \rightarrow 2\chi} v \rangle$  is less straightforward, as this reaction is kinematically forbidden when pions have zero momentum (or at  $T = 0$ ).

In this case, taking the thermal average leads to an exponential suppression of the cross section. For  $x = M_\pi/T$ , we have

$$\langle \sigma_{2\pi \rightarrow 2\chi} v \rangle = \frac{(1 + \Delta)^3}{N_\pi^2} e^{-2\Delta x} \langle \sigma_{2\chi \rightarrow 2\pi} v \rangle. \quad (7)$$

The dark matter relic abundance is set through annihilations to **heavier** states that are kinematically forbidden at  $T = 0$ . This framework is an example of **forbidden** DM Griest & Seckel: PRD **43**, 3191 (1991), D'Agnolo & Ruderman: PRL **115**, 061301 (2015)

# Solving the Boltzmann Equation

We plot solution taking the scale as  $M_\pi = 1$  GeV, with parameters  $M_\pi/F_\pi = 4$ ,  $F_\pi^2/F_d^2 = 0.1$ ,  $\Delta = 0.3$ ,  $\gamma = 3$  and  $y = 2$ .

Plot using convenient variables:

$$Y_\pi = n_\pi/s$$

$$x = M_\pi/T$$

High temp boundary condition

$$Y_\pi(T_i) = n_\pi^{\text{eq}}(T_i)/s(T_i).$$

Before freezeout,  $Y_\pi \approx n_\pi^{\text{eq}}(T)/s(T)$ .

After freezeout  $Y_\pi$  roughly constant.

$$\Omega_{\text{CDM}} h^2 = \frac{M_\pi s_0 Y_\pi(\infty)}{\rho_c/h^2},$$

# Parameter Space

- Bands indicate parameter space for which  $\Omega_{\text{CDM}} h^2$  is within 10% of its observed value.
- Range of DM masses allowed. Lighter than typical WIMPs, due to forbidden mechanism.
- Pale shaded regions excluded due to upper bounds on  $\frac{\sigma}{M_\pi}(\pi\pi \rightarrow \pi\pi)$  e.g. from bullet cluster...

# Coupling to Visible Sector

At the level of dilaton EFT, the necessary couplings take the form

$$\mathcal{L}_{\text{int}} = \epsilon F_d^{4-d_{\text{SM}}} \left( \frac{\bar{\chi}}{F_d} \right) \mathcal{O}_{\text{SM}}, \quad (8)$$

where  $\epsilon$  are weak, dimensionless constants, and  $\mathcal{O}_{\text{SM}}$  are singlet, scalar operators involving light SM fields (e.g  $\mathcal{O} = F_{\mu\nu} F^{\mu\nu}$ ).

- 1 The dilaton couplings are not constrained by the form of the SM energy momentum tensor (as dilaton is a composite of dark sector, and not SM dofs).
- 2 Bounds exist for specific subsets of these couplings from astrophysics, CMB, collider experiments. We leave this for future work.
- 3 We can however derive a more model independent constraint...

# Consistency Condition

- 1 The inclusive decay rate  $\Gamma_{\chi \rightarrow \text{SM}}$  must be large enough to bring the dark sector and SM into thermal equilibrium long before freezeout.
- 2 The decay rate must also be small enough so that direct annihilations  $\pi\pi \rightarrow \text{SM}$  do not overwhelm forbidden annihilations to dilatons.

## Two-Sided Bound on the Inclusive Decay Rate

$$H_{T=M_\pi} \lesssim \Gamma_{\chi \rightarrow \text{SM}} \lesssim H_{T=T_f} \frac{M_\pi N_\pi F_d^2}{n_\pi^{\text{eq}}(T_f)}, \quad (9)$$

# Summary and Outlook

- ➡ We have fitted dilaton EFT to lattice data for a particular near-conformal gauge theory, finding a good fit.

# Summary and Outlook

- ➡ We have fitted dilaton EFT to lattice data for a particular near-conformal gauge theory, finding a good fit.
- ➡ We proposed a description of composite DM based on dilaton EFT.

# Summary and Outlook

- ➡ We have fitted dilaton EFT to lattice data for a particular near-conformal gauge theory, finding a good fit.
- ➡ We proposed a description of composite DM based on dilaton EFT.
- ➡ The DM is the pNGB of a nearly conformal gauge theory, and the dilaton plays the role of a mediator with the standard model.

# Summary and Outlook

- ➡ We have fitted dilaton EFT to lattice data for a particular near-conformal gauge theory, finding a good fit.
- ➡ We proposed a description of composite DM based on dilaton EFT.
- ➡ The DM is the pNGB of a nearly conformal gauge theory, and the dilaton plays the role of a mediator with the standard model.
- ➡ Our framework naturally implements the forbidden dark matter mechanism. The DM is a thermal relic with abundance set by forbidden  $\pi\pi \rightarrow \chi\chi$  annihilations. The framework accommodates a wide range of DM masses:  $M_\pi \sim 10 \text{ MeV} - 100 \text{ GeV}$ .

Thank you!

# Lattice Action

- Our numerical calculations use improved nHYP smeared **staggered** fermions with smearing parameters  $\alpha = (0.5, 0.5, 0.4)$ . [LSD PRD 99(2019)014509]
- $\beta_A/\beta_F = -0.25$  where  $\beta_F = 4.8$ .
- After taste splitting, only  $SU(2)_L \times SU(2)_R$  flavor symmetry preserved in massless theory (3 exact NGBs).
- Spectral study has revealed that the taste splitting of the 63-plet masses are on the order of 20–30%. [LSD PRD 99(2019)014509]

# Summary of Improvements to Lattice Dataset

Presented in 2306.06095

Since the previous LSD study of the  $N_f = 8$  theory PRD **99** (2019) 014509, we have made some changes.

- 1 We have data for a new observable: The scalar decay constant  $F_S$ .
- 2 We have extrapolated the quantities  $M_\pi$ ,  $F_\pi$ ,  $M_\sigma$  (and also  $F_S$ ) to the infinite volume limit.
- 3 We have improved our estimates of systematic uncertainties using Bayesian Model Averaging Jay, Neil PRD **103** (2021) 114502

The  $N_f = 8$  spectrum has also been calculated before in LatKMI PRD **96** (2017) 014508

# Scalar Decay Constant

Measured by LatKMI in PRD 96 (2017) 014508

Define scalar decay constant using the matrix element

$$\langle 0 | J_S(x) | \chi(p) \rangle \equiv F_S M_d^2 e^{-p \cdot x}, \quad (10)$$

where

$$J_S(x) \equiv m \sum_{i=1}^{N_f} \bar{\psi}_i \psi_i. \quad (11)$$

- 1  $F_S$  can be extracted from lattice measurement of correlator  $\langle J_S(x) J_S(0) \rangle$ , which is used already to measure  $M_d$ .
- 2 It is a true decay constant: It would control the decay rate of the dilaton if there was a heavy scalar mediator coupled to  $\bar{\psi}\psi$  along with light states. Analogous to  $f_\pi$  for the QCD pion decaying to leptons via  $W^\pm$ .

# Scalar Decay Constant

This quantity can also be calculated in dilaton EFT:

$$|F_S| = \frac{y N_f M_\pi^2 F_\pi}{2 M_d^2} \frac{f_\pi}{f_d}. \quad (12)$$

- Incorporating Eq. (12) into our EFT fit provides a direct test of the coupling between the light scalar and the fermion mass, treated as an external source.

# Lattice Calculation of Scattering Phase Shift

Phys.Rev.D **105** (2022) with LSD Collaboration

M. Lüscher NPB 354 (1991)

$$k^2 = \frac{1}{4}E_{\pi\pi}^2 - M_\pi^2 \quad (13)$$

$$k \cot \delta(k) = \frac{2\pi}{L}\pi^{-3/2}Z_{00} \left(1, \frac{k^2 L^2}{4\pi^2}\right) \quad (14)$$

- Restrict ourselves to  $l = 2$  channel.
- $E_{\pi\pi}$  is the two-PNGB ground state energy.
- Measured at finite volume ( $L$ ) on the lattice from a fit to a two point correlation function of two PNGB operators. Schematically:  
 $C(t) \sim \langle \mathcal{O}^{l=2}(t) \mathcal{O}^{\dagger l=2}(0) \rangle$  where  $\mathcal{O}^{l=2} \sim \pi\pi$ .

# $l = 2$ Scattering Length

- Scattering amplitude at threshold =  $M_\pi a^{l=2}$
- First diagram, same as  $\chi$ PT. The others only arise for light scalar (dilaton).

$$M_\pi a^{l=2} = -\frac{M_\pi^2}{16\pi F_\pi^2} \left( 1 - (y-2)^2 \frac{f_\pi^2}{f_d^2} \frac{M_\pi^2}{M_d^2} \right). \quad (15)$$

Simplifies to  $\chi$ PT result when  $y \rightarrow 2$  or  $f_\pi^2/f_d^2 \rightarrow 0$ .

# Scaling Relations at Leading Order

We also want to test the alternate possibility - that the  $N_f = 8$  theory is *inside* the conformal window.

Assuming the gauge coupling  $g$  has reached its fixed point value  $g^*$ , physical quantities may be fitted to scaling relations Zwicky, del Debbio PLB **700** (2011)

$$M_X = C_X m^{[1/(1+\gamma^*)]} , \quad (16)$$

$$F_Y = C_Y m^{[1/(1+\gamma^*)]} , \quad (17)$$

$$1/a_0^{(2)} = C_a m^{[1/(1+\gamma^*)]} . \quad (18)$$

# Result of Global Fit to Mass-Deformed CFT

Fitting to the same set of lattice data as in the dilaton case, we find:

Parameter	Value and Uncertainty
$C_{M_\pi}$	2.121(78)
$C_{F_\pi}$	0.522(19)
$C_{M_d}$	2.97(12)
$C_{F_S}$	0.706(33)
$C_a$	-5.88(22)
$\gamma^*$	1.073(28)
$\chi^2/\text{dof}$	48.1/19 = 2.53

The  $\chi^2/\text{dof}$  is larger than for the dEFT fit, while the number of fit parameters is the same. This indicates a lower quality fit.

# Marginality Crossing

Gies and Jaeckel: Eur.Phys.J.C46 (2006)

Kaplan, Lee, Son and Stephanov: Phys.Rev.D80 (2009)

Gukov: Nucl.Phys.B.919 (2017)

$$\mathcal{L} = \frac{1}{4} \text{Tr} [G_{\mu\nu} G^{\mu\nu}] + \sum_i \bar{\psi}_i \not{D} \psi_i + \mathcal{L}_{4 \text{ fermi}} \quad (19)$$

The conformal window is exited when a 4 fermi operator becomes relevant.

# Freezeout Temperature
