Top Physics aims

I. Measure all properties (mass, couplings, spin) to establish **indirect** evidence for SM and BSM physics.

Precision EW and QCD;
Rare decays and anomalous couplings. Flavor Physics.
CP violation.

II. Use top as **direct** probe of the EWSB sector and BSM physics

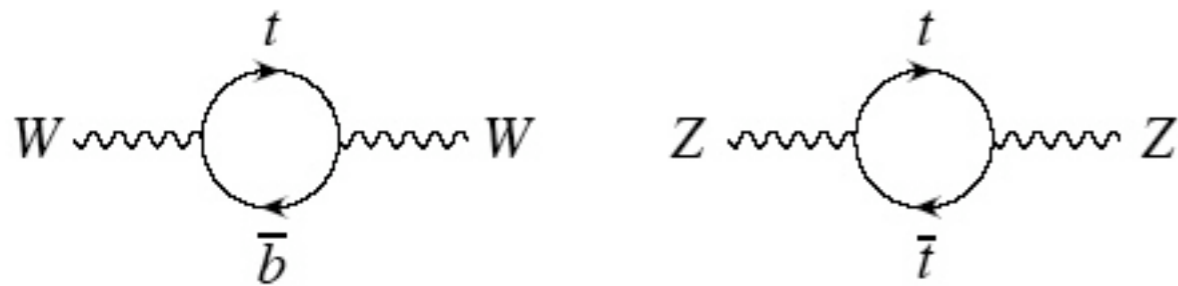

SM : ttH ; tH
BSM: Z' and W' resonances;
SUSY: tH^+ and $t \rightarrow bH^+$ or $stop \rightarrow t X$.

Top Physics aims I : precision EW

Indirect evidence for the existence of particles not yet detected can be inferred from quantum corrections. At tree level $m_W = m_Z \cos \theta_W$. At one loop:

$$m_W^2 \left(1 - \frac{m_W^2}{m_Z^2} \right) = \frac{\pi\alpha}{\sqrt{2}G_F} (1 + \Delta r)$$

$$\Delta r_{\text{top}} = - \frac{3\alpha \cos^2 \theta_W}{16\pi \sin^4 \theta_W} \frac{m_t^2}{m_W^2}$$

$$\Delta r_{\text{Higgs}} = + \frac{11\alpha}{48\pi \sin^2 \theta_W} \log \frac{m_H^2}{m_W^2}$$

m_W [GeV]

Top Physics aims I : precision EW

Beyond the SM precision measurements can be also very useful. For instance in SUSY, the corrections to the Higgs mass are given by:

$$\Delta M^2 \simeq G_F m_t^4 \log \frac{m_{\tilde{t}_1} m_{\tilde{t}_2}}{m_t^2}$$

In fact top effects can be really important in theories like SUSY: Large and negative 1-loop corrections can turn the Higgs mass parameters negative and even trigger ESWB.

Top Physics aims II : direct probe

Exciting the Higgs

Exciting new degrees of freedom

Top as a link to BSM

The top quark dramatically affects the stability of the Higgs mass.
Consider the SM as an effective field theory valid up to scale Λ :

$$m_H^2 = m_{H0}^2 - \frac{3}{8\pi^2} y_t^2 \Lambda^2 + \frac{1}{16\pi^2} g^2 \Lambda^2 + \frac{1}{16\pi^2} \lambda^2 \Lambda^2$$

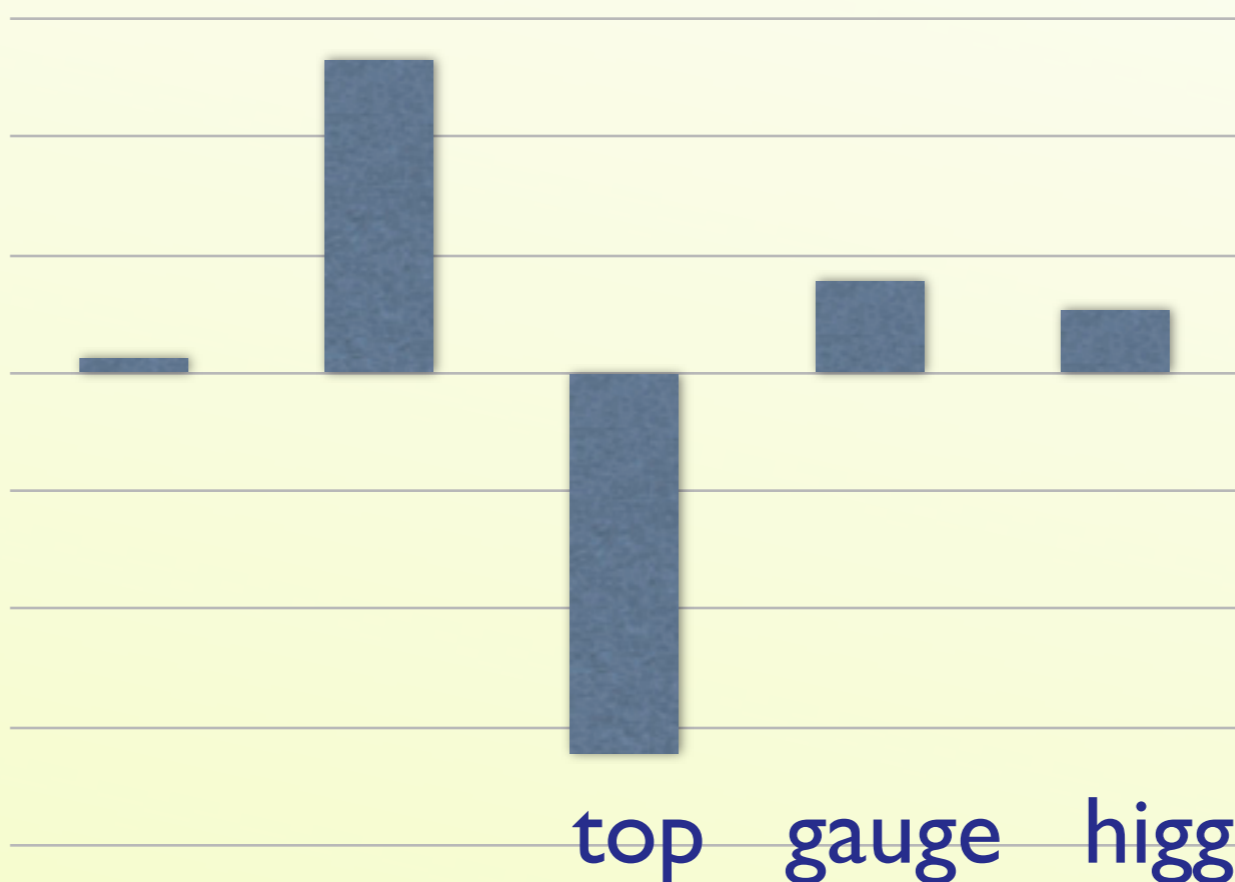

Putting numbers, I have:

$$(200 \text{ GeV})^2 = m_{H0}^2 + [-(2 \text{ TeV})^2 + (700 \text{ GeV})^2 + (500 \text{ GeV})^2] \left(\frac{\Lambda}{10 \text{ TeV}} \right)^2$$

Top as a link to BSM

tree

loops

$$m_h^2 \sim (200 \text{ GeV})^2$$

$$(200 \text{ GeV})^2 = m_{H_0}^2 + [-(2 \text{ TeV})^2 + (700 \text{ GeV})^2 + (500 \text{ GeV})^2] \left(\frac{\Lambda}{10 \text{ TeV}} \right)^2$$

Definition of naturalness: less than 90% cancellation:

$$\Lambda_t < 3 \text{ TeV} \quad \Lambda_t < 9 \text{ TeV} \quad \Lambda_t < 12 \text{ TeV}$$

One can actually prove that this case in model independent way, i.e. that the scale associated with top mass generation is very close to that of EWSB =>

First new physics could be associated with top!!

Available solutions

There have been many different suggestions! Fortunately, we can say that they group in 1+3 large classes:

1. **Denial:** There is no problem. Naturalness is our problem not Nature's. Pro's: we'll find the Higgs. Cons: that's it.
2. **Weakly coupled model at the TeV scale:**
Introduce new particles to cancel SM "divergences".
3. **Strongly coupled model at the TeV scale:**
New strong dynamics enters at ~ 1 TeV.
4. **New space-time structure:**
Introduce extra space dimensions to lower the Planck scale cutoff to 1 TeV.

Top is the only natural quark

Top partners, new scalars/vectors possibly strongly coupled with top.

Top: t-tbar bound states, colorons.

KK-excitations

Top as a template

VS

Both involve production of heavy colored states decaying through a chain into jets, leptons and \cancel{E}_T .

Top as background

At the LHC, many measurements will need a good understanding and control of $t\bar{t}$ and single top events.

A few examples:

- $gg \rightarrow H$ and $qq \rightarrow Hqq$ with $H \rightarrow WW$
- $t\bar{t}$ in single top measurements
- $t\bar{t}$ +jets and $t\bar{t}b\bar{b}$ in $t\bar{t}H$
- $t\bar{t}$ +jets in SUSY/UED searches (gluino pairs, stop pairs, tH^+)
-

Outline

- The importance of being **Top**
- Truth and myths about **Top**
- **Top** in the making

Charmonium is there, Bottomonium is there, what about Toponium?

Unfortunately, top decays too fast for bound states to form...

Radiation in top events? Everybody knows that top does not like to radiate a lot...

Measuring the top spin effects will prove that hadronization does not place!

Have you heard of the latest top mass measurement?..

Which mass?

Vtb? I just measure it in top decays!

I don't understand why everybody gets so excited about Top: is just a quark like the others!

Basic facts about top

- It is the $SU(2)_L$ partner of the bottom.
- $t_L \Rightarrow T^3 = +1/2$, t_R singlet.
- Its mass is obtained in the EWSB.
- $Q_t = +2/3$ and is a color triplet.
- All couplings are fixed by the gauge structure.

Basic facts about top

- It is the $SU(2)_L$ partner of the bottom.
- $t_L \Rightarrow T^3 = +1/2$, t_R singlet.
- Its mass is obtained in the EWSB.
- $Q_t = +2/3$ and is a color triplet.
- All couplings are fixed by the gauge structure.

It is just as all other (up) quarks: what's so special about it?

Truth or Myth #1 : “Top is special”

In the SM, it is the ONLY quark

Truth or Myth #1 : “Top is special”

In the SM, it is the ONLY quark

1. with a “natural mass”:

$$m_{\text{top}} = y_t v / \sqrt{2} \approx 174 \text{ GeV} \Rightarrow y_t \approx 1$$

It “strongly” interacts with the Higgs sector. This also suggests that top might have special role in the mechanism of EWSB and/or fermion mass generation.

Truth or Myth #1 : “Top is special”

In the SM, it is the ONLY quark

1. with a “natural mass”:

$$m_{\text{top}} = y_t v / \sqrt{2} \approx 174 \text{ GeV} \Rightarrow y_t \approx 1$$

It “strongly” interacts with the Higgs sector. This also suggests that top might have special role in the mechanism of EWSB and/or fermion mass generation.

2. that decays before hadronizing

$$\tau_{\text{had}} \approx h / \Lambda_{\text{QCD}} \approx 2 \cdot 10^{-24} \text{ s}$$

$$\tau_{\text{top}} \approx h / \Gamma_{\text{top}} = 1 / (G_F m_t^3 |V_{tb}|^2 / 8\pi\sqrt{2}) \approx 5 \cdot 10^{-25} \text{ s}$$

(with $h = 6.6 \cdot 10^{-25} \text{ GeV s}$)

(Compare with $\tau_b \approx (G_F^2 m_b^5 |V_{bc}|^2 k)^{-1} \approx 10^{-12} \text{ s}$)

Truth or Myth #1 : “Top is special”

In the SM, it is the ONLY quark

1. with a “natural mass”:

$$m_{\text{top}} = y_t v / \sqrt{2} \approx 174 \text{ GeV} \Rightarrow y_t \approx 1$$

It “strongly” interacts with the Higgs sector. This also suggests that top might have special role in the mechanism of EWSB and/or fermion mass generation.

2. that decays before hadronizing

$$\tau_{\text{had}} \approx h / \Lambda_{\text{QCD}} \approx 2 \cdot 10^{-24} \text{ s}$$

$$\tau_{\text{top}} \approx h / \Gamma_{\text{top}} = 1 / (G_F m_t^3 |V_{tb}|^2 / 8\pi \sqrt{2}) \approx 5 \cdot 10^{-25} \text{ s}$$

(with $h = 6.6 \cdot 10^{-25} \text{ GeV s}$)

(Compare with $\tau_b \approx (G_F^2 m_b^5 |V_{bc}|^2 k)^{-1} \approx 10^{-12} \text{ s}$)

What do we really know about top?

Quantity	Uncertainty	Measurement	Useful for...
Mass	<1%	invariant mass	EW fits (Higgs and BSM)
Spin	consistent	decay products	BSM?
charge	-4/3 excluded	decay products	BSM?

Top mass history

Such a heavy top was a surprise. However, the lower limit had been increasing and there had been hints from analysis of electroweak data, where the top mass enters via loop corrections.

Top mass history

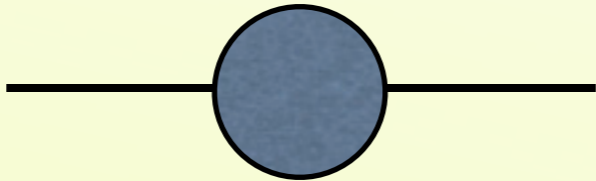

Such a heavy top was a surprise. However, the lower limit had been increasing and there had been hints from analysis of electroweak data, where the top mass enters via loop corrections.

Mass definition

The **top mass** is so precisely measured ($m_t = 171.2 \pm 1.5$ GeV) that we have to worry about its definition.

Leading order:  $\frac{1}{\not{p} - m}$ (pole) mass = m

Higher orders:  $\frac{1}{\not{p} - m_R - \Sigma(\not{p})}$ $m_R =$ renor. mass

(At least) two possible renormalisation schemes: **$\overline{\text{MS}}$** and **on-shell**, leading to different mass definitions.

The **$\overline{\text{MS}}$ mass** is a fully perturbative object, not sensitive to long-distance dynamics. It can be determined as precisely as the perturbative calculation allows. The mass is thought as any other parameter in the Lagrangian. It is the same as the Yukawa coupling. For example, it could be extracted from a cross section measurement.

Mass definition

The **pole mass** would be more physical (pole = propagation of particle, though a quark doesn't usually really propagate -- hadronisation!) but is affected by long-distance effects: **it can never be determined with accuracy better than Λ_{QCD}** .

The **pole mass** is closer to what we measure at colliders through invariant mass of the top decay products. The ambiguities in that case are explicitly seen in the modeling of extra radiation, the color connect effects and hadronization.

The two masses can be related perturbatively (modulo non-perturbative corrections!!):

$$m_{pole} = \bar{m}(\bar{m}) \left(1 + \frac{4}{3} \frac{\bar{\alpha}_s(\bar{m})}{\pi} + 8.28 \left(\frac{\bar{\alpha}_s(\bar{m})}{\pi} \right)^2 + \dots \right) + O(\Lambda_{\text{QCD}})$$

Truth or Myth #2 : “ V_{tb} can be measured from top decay rates”

The argument goes as follows.

The number of events where the top decays into b jets is given by

$$N_{\text{events}} = (\mathcal{L} \cdot \epsilon) \sigma(tt\bar{t}) \cdot \frac{\Gamma(t \rightarrow Wb)}{\sum_q \Gamma(t \rightarrow Wq)} = (\mathcal{L} \cdot \epsilon) \sigma(tt\bar{t}) \cdot |V_{tb}|^2$$

where we have used unitarity of the CKM:

$$|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2 = 1$$

The top cross section depends only on QCD and top mass and can be given by theory.
Lumi and efficiencies are exp. determined.

Do you agree?

Vtb intermezzo

Let's remind ourselves what the CKM matrix actually is

$$J_{\mu}^{+} = \bar{u}_L \gamma_{\mu} d_L \quad \text{mass eigenstates} \quad \Rightarrow \quad J_{\mu}^{+} = \bar{U}_L \gamma_{\mu} V_{\text{CKM}} D_L$$

By fitting all the information we have available mostly from K^0 - \bar{K}^0 mixing, B-physics:

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 0.9739 - 0.9751 & 0.221 - 0.227 & 0.0029 - 0.0045 \\ 0.221 - 0.227 & 0.9730 - 0.9744 & 0.039 - 0.044 \\ 0.0048 - 0.014 & 0.037 - 0.043 & 0.9990 - 0.9992 \end{pmatrix}$$

Vtb intermezzo

Let's remind ourselves what the CKM matrix actually is

$$J_{\mu}^{+} = \bar{u}_L \gamma_{\mu} d_L \quad \text{mass eigenstates} \quad \Rightarrow \quad J_{\mu}^{+} = \bar{U}_L \gamma_{\mu} V_{\text{CKM}} D_L$$

By fitting all the information we have available mostly from K^0 - \bar{K}^0 mixing, B-physics:

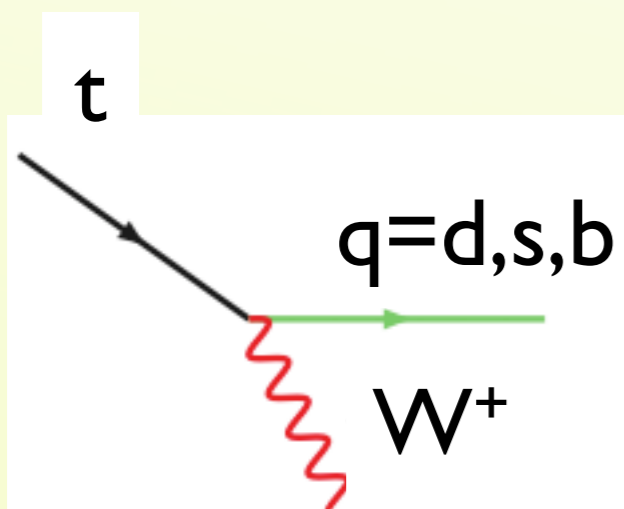

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \Rightarrow \begin{pmatrix} 0.9730 - 0.9746 & 0.2174 - 0.2241 & 0.0030 - 0.0044 \dots \\ 0.213 - 0.226 & 0.968 - 0.975 & 0.039 - 0.044 \dots \\ 0 & -0.08 & 0 & -0.11 & 0.07 & -0.9993 \dots \\ & \vdots & & \vdots & & \vdots \end{pmatrix}$$

However most of such information, does not tell us anything directly on the last row. It is the hypothesis of unitarity of the CKM which constraints the V_{ti} matrix elements. For example the last measurements from CDF on B_s - B_s mixing gives

$$0.20 < |V_{td}/V_{ts}| < 0.22$$

Truth or Myth #2 :

“ V_{tb} can be measured from top decay rates”

Counter arguments:

1. Assuming 3 generation unitarity leaves OUT the interesting BSM physics that this measurement explores (4th generation)
 In addition within 3 generation, $V_{tb} = 0.999...!!!$

2. Number of events is proportional to the Branching ratio,

$$R = \frac{\Gamma(t \rightarrow Wb)}{\sum_{light} \Gamma(t \rightarrow Wq)} = \frac{|V_{tb}|^2}{|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2}$$

where we already know that $V_{td}, V_{ts} \ll V_{tb}$, so $R \sim 1$
 independently of the overall scale of V_{td}, V_{ts}, V_{tb} and basically independent of V_{tb} .

Conclusion: V_{tb} cannot be measured from the decay of the top. From where then? You need quantities (almost) proportional to $|V_{tb}|^2$ only. Two possibilities:

1. The width of the top
2. Single top cross section

Truth or Myth #2 :

“ V_{tb} can be measured from top decay rates”

Counter arguments:

1. Assuming 3 generation unitarity leaves OUT the interesting BSM physics that this measurement explores (4th generation)
 In addition within 3 generation, $V_{tb} = 0.999...!!!$

1. The width of the top
2. Single top cross section

W polarization

The SM vertex of the top decay implies that it's only the t_L that takes part to the interaction.

This has straightforward consequences on the possible helicity states of the on-shell W produced in the decay.

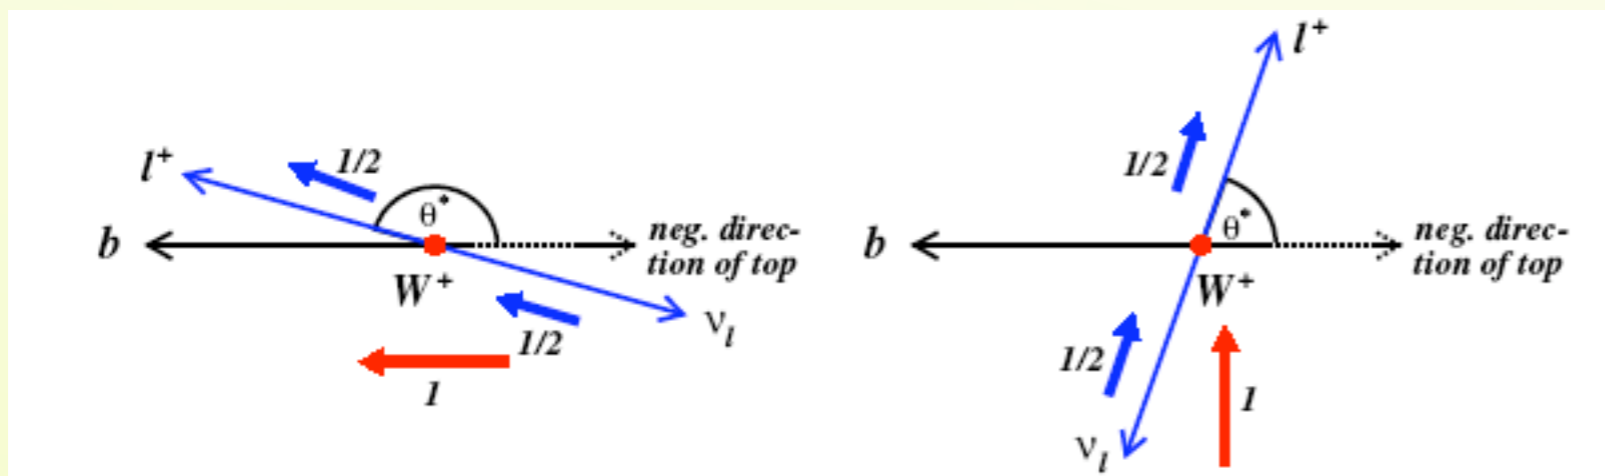

Neglecting m_b , this implies that the W can be only either longitudinally polarized or with negative helicity

How do we measure it?? The W polarization is inherited by its decay products, which “remember it” in their angular distributions.

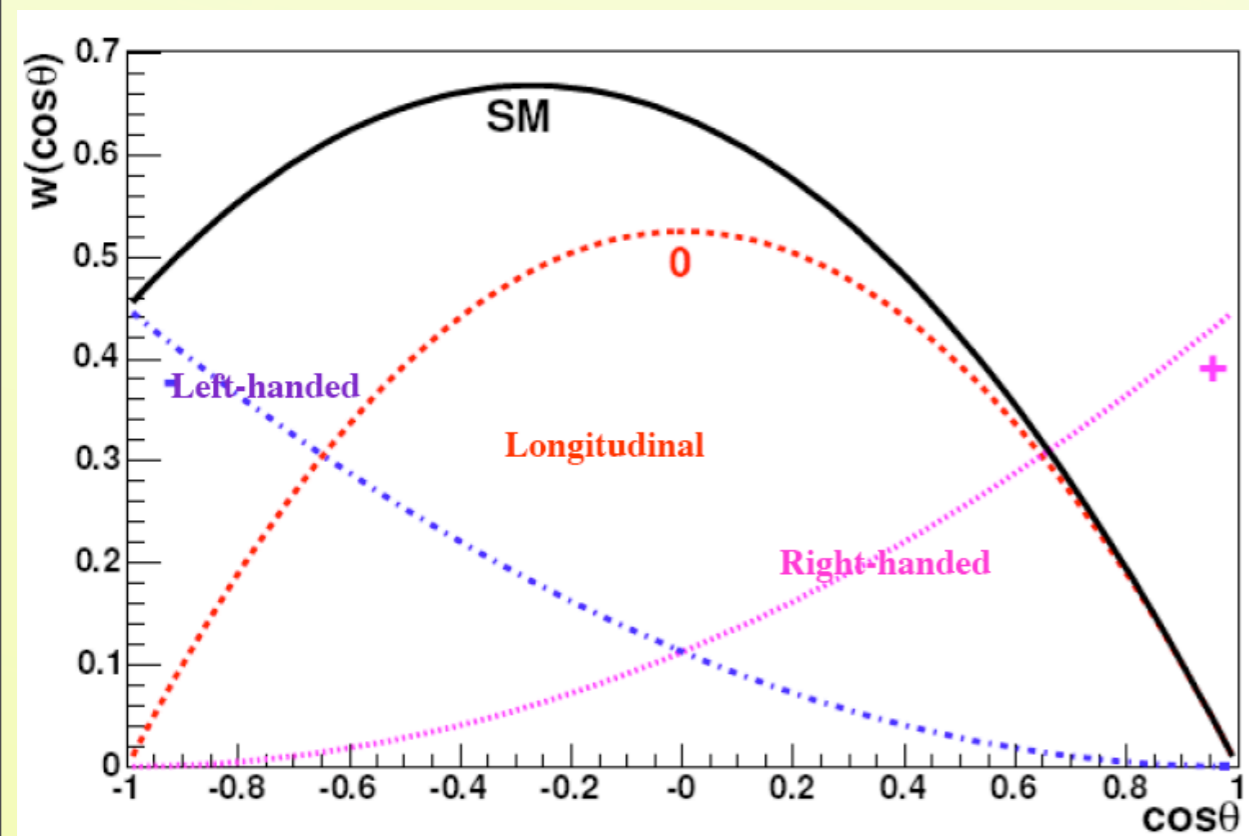

W polarization

$$\frac{1}{N} \frac{dN(W \rightarrow l\nu)}{d\cos\theta} = K [f_0 \sin^2 \theta + f_L (1 - \cos \theta)^2 + f_R (1 + \cos \theta)^2]$$

$$f_0 = \frac{m_t^2}{2m_W^2 + m_t^2} = 70\%$$

Fraction of longitudinal W's
(basically the only ones we see in a pp collider!)

* The formula above is already not trivial since it says that W polarizations don't interfere! (This is true only for 1 dim distributions!)

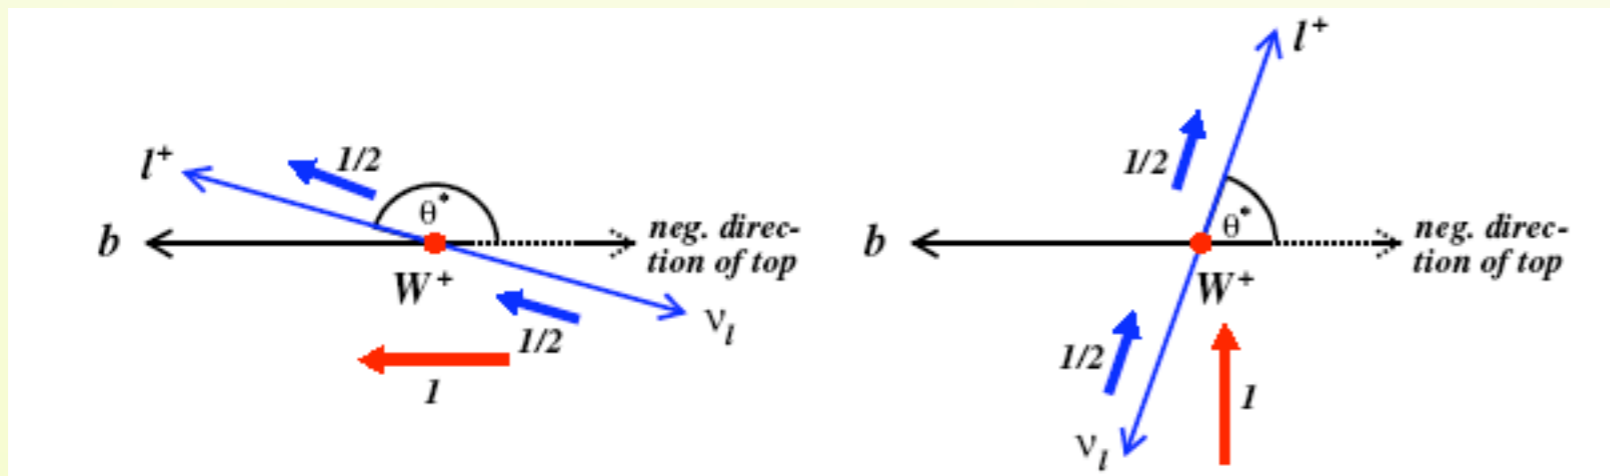

* Longitudinal polarization come from the Higgs doublet (charged component).

* $\cos(\theta)$, which is defined in a specific frame, can be related to $m(\text{lepton, bottom})$ or $p_t(\text{lepton})$, ergo **no top momentum reconstruction necessary!**

* Rather "easy measurement".

W polarization

$$\frac{1}{N} \frac{dN(W \rightarrow l\nu)}{d\cos\theta} = K [f_0 \sin^2 \theta + f_L (1 - \cos \theta)^2 + f_R (1 + \cos \theta)^2]$$

$$f_0 = \frac{m_t^2}{2m_W^2 + m_t^2} = 70\%$$

Fraction of longitudinal W's
(basically the only ones we see in a pp collider!)

* The formula above is already not trivial since it says that W polarizations don't interfere! (This is true only for 1 dim distributions!)

* Longitudinal polarization come from the Higgs doublet (charged component).

* $\cos(\theta)$, which is defined in a specific frame, can be related to $m(\text{lepton, bottom})$ or $p_t(\text{lepton})$, ergo **no top momentum reconstruction necessary!**

* Rather "easy measurement".

Truth or Myth #3 :

“no hadronization \Rightarrow no resonance physics”

Consider how the charm and the bottom quarks were discovered:

$$2S+1 L_J^{[C]} = 3 S_1^{[1]}$$

Very sharp peaks \Rightarrow small widths (~ 100 KeV) compared to hadronic resonances (100 MeV) \Rightarrow very long lived states. QCD is “weak” at scales $\gg \Lambda_{\text{QCD}}$ (asymptotic freedom), non-relativistic bound states are formed like positronium!

The QCD-Coulomb potential is like

$$V(r) \simeq -C_F \frac{\alpha_S(1/r)}{r} \quad C_F = 4/3$$

Truth or Myth #3 :

“no hadronization \Rightarrow no resonance physics”

Let analyse the scales which characterise the bound state. The scales can be found using the the enegy of the ground state and the virial theorem:

$$E_0 = -\frac{1}{2} \frac{m_t}{2} (C_F \alpha_S)^2 \quad \text{with} \quad \langle T \rangle = -\frac{1}{2} \langle V \rangle \quad \text{gives} \quad v \simeq C_F \alpha_S (mv)$$

$$R_0 = 1 / (C_F \alpha_S m_t / 2)$$

Scale	Quantity	e+e-	toponium
m	annihilation time	0.5 MeV	172 GeV
mv	size $p \sim 1/R$	3.7 KeV	15 GeV
mv ²	Formation time	25 eV	2 GeV

This equation can be solved iteratively and gives scales that are all perturbative and well separated.

“Unfortunately” the formation time for the bound state is

$$\tau_{\text{form}} \approx \text{size}/v \approx mv^2 \approx 1/(2 \text{ GeV})$$

$$\tau_{\text{weakdecay}} \approx \tau_{\text{top}}/2 \approx 1/(3 \text{ GeV}) < \tau_{\text{form}}$$

So..... no resonance physis???

Truth or Myth #3 :

“no hadronization \Rightarrow no resonance physics”

The time scales, formation and decay, are not so widely different (by chance!). Therefore if we perform a threshold scan in e^+e^- we should be able to see an enhancement of the cross section, due to Coulomb rescattering. The width of the peak is proportional to the width (direct measurement) and the position of the peak would allow a very precise mass measurement. A serious calculation gives:

Can something similar happen in pp collisions? It's a good question!...Stay tuned!!

Myth

Truth or Myth #3 :

“no hadronization \Rightarrow no resonance physics”

The time scales, formation and decay, are not so widely different (by chance!). Therefore if we perform a threshold scan in e^+e^- we should be able to see an enhancement of the cross section, due to Coulomb rescattering. The width of the peak is proportional to the width (direct measurement) and the position of the peak would allow a very precise mass measurement. A serious calculation gives:

Can something similar happen in pp collisions? It's a good question!...Stay tuned!!

Truth or Myth #4 : “No hadronization \Leftrightarrow Top spin effects”

We have now very clear that most probably (if V_{tb} is indeed 1) top decays before hadronizing,

$$\tau_{\text{had}} \approx h/\Lambda_{\text{QCD}} \approx 2 \cdot 10^{-24} \text{ s} > \tau_{\text{top dec}} \approx h/\Gamma_{\text{top}} 5 \cdot 10^{-25} \text{ s}$$

Therefore non-perturbative effects (soft-gluons) don't have the time to change the spin of the top which is then passed from the production to the decay. As a result the spin becomes a typical quantum mechanical quantity and correlation measurements can be performed (see tomorrow).

HOWEVER, one can also ask : Is the opposite true? if we see spin correlation effects do we automatically put an upper bound on the width and hadronization? NO!

Spin-flips are due to CHROMOMAGNETIC interactions, which are mediated by dimension 5 operators:

$$\mathcal{L}_{\text{mag}} = \frac{C_m}{4m_t} \bar{Q}_v G_{\mu\nu} \sigma^{\mu\nu} Q_v \Rightarrow \tau_{\text{flip}} \simeq h \left(\frac{\Lambda_{\text{QCD}}^2}{m_t} \right)^{-1} \gg \tau_{\text{had}}$$

If, for instance, $V_{tb} \sim 0.3$, then top would start hadronizing into mesons and still conserve its spin!

[Falk and Peskin, 1994]

Truth or Myth #4 : “No hadronization \Leftrightarrow Top spin effects”

We have now very clear that most probably (if V_{tb} is indeed 1) top decays before hadronizing,

$$\tau_{\text{had}} \approx h/\Lambda_{\text{QCD}} \approx 2 \cdot 10^{-24} \text{ s} > \tau_{\text{top dec}} \approx h/\Gamma_{\text{top}} 5 \cdot 10^{-25} \text{ s}$$

Therefore non-perturbative effects (soft-gluons) don't have the time to change the spin of the top which is then passed from the production to the decay. As a result the spin becomes a typical quantum mechanical quantity and correlation measurements can be performed (see tomorrow).

HOWEVER, one can also ask : Is the opposite true? if we see spin correlation effects do we automatically put an upper bound on the width and hadronization? NO!

Spin-flips are due to CHROMOMAGNETIC interactions, which are mediated by dimension 5 operators:

$$\mathcal{L}_{\text{mag}} = \frac{C_m}{4m_t} \bar{Q}_v G_{\mu\nu} \sigma^{\mu\nu} Q_v \Rightarrow \tau_{\text{flip}} \simeq h \left(\frac{\Lambda_{\text{QCD}}^2}{m_t} \right)^{-1} \gg \tau_{\text{had}}$$

If, for instance, $V_{tb} \sim 0.3$, then top would start hadronizing into mesons and still conserve its spin!

[Falk and Peskin, 1994]

How to measure top spin

In particular one can easily show that for the top, the lepton⁺ (or the d), in the top rest frame, tends to be emitted in the same direction of the top spin.

Note that this has nothing to do with W polarization! In particular one studies spin correlations between the top and anti-top in $t\bar{t}$ production and the spin of the top in single top.

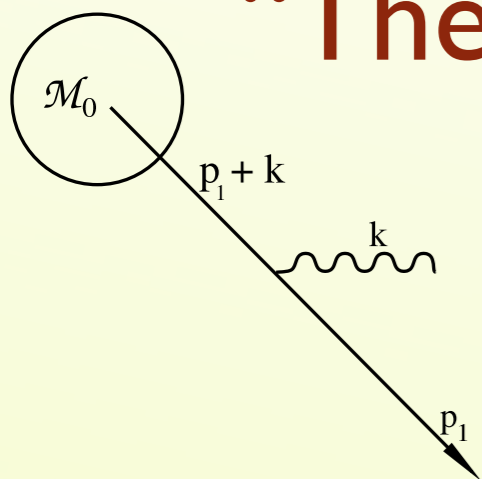

Results depend on the degree of polarization (p) of the tops themselves and from the choice of the “spin-analyzer” k_i .

	l^+	d	u	b	$j_<$	\mathbf{T}	$j_>$
LO:	1	1	-0.32	-0.39	0.51	-0.32	0.2
NLO:	0.999	0.97	-0.31	-0.37	0.47	-0.31	

$$\frac{1}{\Gamma} \frac{d\Gamma}{d \cos \theta} = \frac{1 + p k_i \cos \theta}{2}$$

Truth or Myth #5 :

“The top does not like to radiate much”

Consider gluon emission off a heavy quark using perturbation theory:

$$D^{\text{real}}(x, k_{\perp}^2, m^2) = \frac{C_F \alpha_S}{2\pi} \left[\frac{1+x^2}{1-x} \frac{1}{k_{\perp}^2 + (1-x)^2 m^2} - x(1-x) \frac{2m^2}{(k_{\perp}^2 + (1-x)^2 m^2)^2} \right]$$

In the massless case ($m=0$) we have a non-integrable collinear singularity:

$$\int_0^1 D(x, k_{\perp}^2) dk_{\perp}^2 = \frac{1+x^2}{1-x} \int_0^1 \frac{dk_{\perp}^2}{k_{\perp}^2} = \infty$$

The presence of the heavy quark mass suppresses the collinear radiation at small transverse momenta and allows the integration down to zero.

Be careful because it's a frame dependent statement!

Truth

Truth or Myth #5 :

“The top does not like to radiate much”

Consider gluon emission off a heavy quark using perturbation theory:

$$D^{\text{real}}(x, k_{\perp}^2, m^2) = \frac{C_F \alpha_S}{2\pi} \left[\frac{1+x^2}{1-x} \frac{1}{k_{\perp}^2 + (1-x)^2 m^2} - x(1-x) \frac{2m^2}{(k_{\perp}^2 + (1-x)^2 m^2)^2} \right]$$

In the massless case ($m=0$) we have a non-integrable collinear singularity:

$$\int_0^1 D(x, k_{\perp}^2) dk_{\perp}^2 = \frac{1+x^2}{1-x} \int_0^1 \frac{dk_{\perp}^2}{k_{\perp}^2} = \infty$$

The presence of the heavy quark mass suppresses the collinear radiation at small transverse momenta and allows the integration down to zero.

Be careful because it's a frame dependent statement!

Truth or Myth #5 :

In the massless case ($m=0$) we have a non-integrable collinear singularity:

$$\int_0^1 D(x, k_{\perp}^2) dk_{\perp}^2 = \frac{1+x^2}{1-x} \int_0^1 \frac{dk_{\perp}^2}{k_{\perp}^2} = \infty$$

The presence of the heavy quark mass suppresses the collinear radiation at small transverse momenta and allows the integration down to zero.

Be careful because it's a frame dependent statement!

Outline

- The importance of being **Top**
- Truth and myths about **Top**
- **Top** in the making

Producing Top

Strong

Largest cross section (LO at α_s^2):

~ 10 pb at Tevatron

~ 1 nb at the LHC

Top discovery mode.

Weak

Weak process : same diagrams as the top decay!

Cross sections smaller than QCD but enhanced by a lower energy cost:

~ 2 pb at Tevatron

~ 300 pb at the LHC

Three independent channels.

At the Tevatron $\sigma(t) = \sigma(t\bar{t})$. At the LHC $\sigma(t) > \sigma(t\bar{t})$ (for s- and t-)

From Tevatron to LHC

Tevatron

85% of the total cross section

10 $t\bar{t}$ pairs per day

60% of the time there is extra radiation so that $p_T(t\bar{t}) > 15$ GeV.

$t\bar{t}$ are produced closed to threshold, in a $^3S_1^{[8]}$ state. Same spin directions. 100% correlated in the off-diagonal basis.

Worry because of the backgrounds: (W +jets, WQ +jets, WW +jets)

LHC

90% of the total cross section

1 $t\bar{t}$ pair per second

Almost 70% of the time there is extra radiation so that $p_T(t\bar{t}) > 30$ GeV.

$t\bar{t}$ can be easily produced away from threshold. On threshold they are $^1S_0^{[1,8]}$ state with opposite spin directions. No 100% correlation.

Background free*!

*Conditions apply. Consult with your local top expert before signing.

Cross sections : from Tevatron to the LHC

Total cross section for $t\bar{t}$ increases by a factor of 100, while Drell-Yan only by a factor of 10.

Top will be one of the major background to any new physics!

However, extra hard radiation is much easier at the LHC than at the Tevatron!

pb	$t\bar{t}$	$W^{+-} \rightarrow e^{+-} \nu_e$ inclusive	$Z \rightarrow e^+ e^-$ inclusive	$W \rightarrow e^{+-} \nu_e$ + 4jets		$Z \rightarrow e^+ e^-$ + 4jets	
TeV	7.6	2000	200	0.98		0.096	
LHC	910	18500	1800	220	(20)	21	(2.1)
Gain	120	9	9	220	(21)	220	(22)

$pt(j) > 20$ (50) GeV, $|\eta(j)| < 3$, $\Delta R(jj) > 0.7$

Master QCD formula

$$\sigma_X = \sum_{a,b} \int_0^1 dx_1 dx_2 f_a(x_1, \mu_F^2) f_b(x_2, \mu_F^2) \times \hat{\sigma}_{ab \rightarrow X}(x_1, x_2, \alpha_S(\mu_R^2), \frac{Q^2}{\mu_F^2}, \frac{Q^2}{\mu_R^2})$$

Two ingredients necessary:

1. Parton Distribution functions (from exp, but evolution from th).
2. Short distance coefficients as an expansion in α_S (from th).

$$\hat{\sigma}_{ab \rightarrow X} = \sigma_0 + \alpha_S \sigma_1 + \alpha_S^2 \sigma_2 + \dots$$

Top @ Tevatron

Standard procedure: vary renormalisation and factorisation scales.

(NLO+NLL, $m=175$ GeV)

But, better do so independently

$$\sigma: 6.82 > 6.70 > 6.23 \text{ pb}$$

$$0.5 < \mu_{R,F}/m < 2$$

$$\sigma: 6.97 > 6.70 > 6.23 \text{ pb}$$

$$0.5 < \mu_{R,F}/m < 2 \ \&\& \ 0.5 < \mu_R/\mu_F < 2$$

“Fiducial” region

Order $\pm 5\%$ uncertainty along the diagonal, a little more considering independent scale variations

BTW, the PDF uncertainty ($\pm 10-15\%$) is probably the dominant one here

Top @ LHC

[Cacciari et al., 2008]

σ : 970 > 908 > 860 pb

$0.5 < \mu_{R,F}/m < 2$

σ : 990 > 908 > 823 pb

$0.5 < \mu_{R,F}/m < 2 \ \&\& \ 0.5 < \mu_R/\mu_F < 2$

[Moch and Uwer, 2008]

The inclusion of leading terms that appear at NNLO seem to sizably reduce the errors!

$m_{t\bar{t}}$ spectrum at the LHC

low invariant mass

- * ~90% of the total cross section
- * $t\bar{t}$ at threshold in a $1S0[t\bar{t}]$ state
- * Shape very sensitive to the top mass
- * High-statistics sample \Rightarrow
 - early SM physics
 - top rare decays
 - low mass new resonances

high invariant mass

- * $m_{t\bar{t}} > 1 \text{ TeV} \Rightarrow \sim 2\%$ of the total cross section
- * Events are more 2jet like \Rightarrow different selection
- * EW effects (e.g. P-violation) start to be important
- * Relevance of $qq+qg$ increases
- * TeV Resonances searches
- * Top partners searches

Truth or Myth #3b:

“Resonance physics only accessible at the ILC”

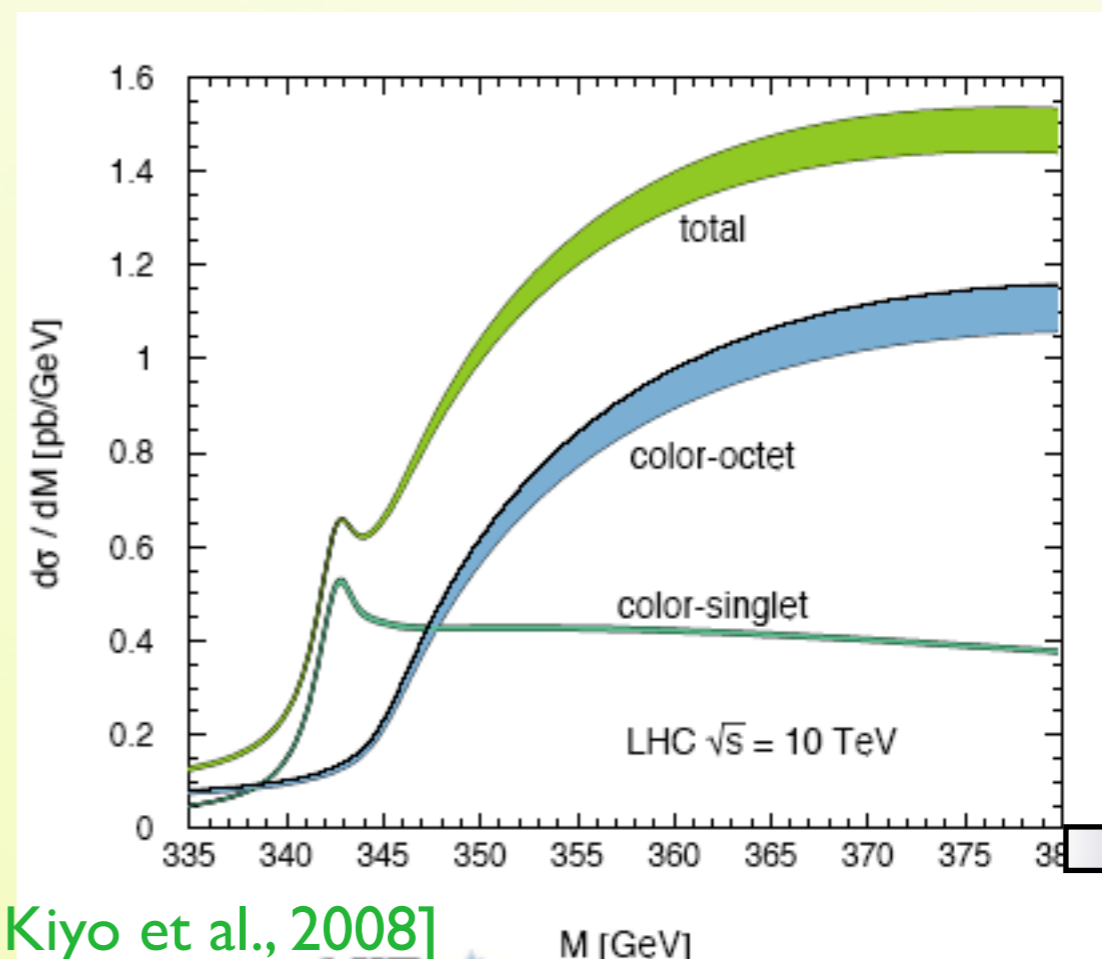

In hadronic collision, the interactions at threshold can be either attractive or repulsive! Octet larger cross section, but “bound state” effects are dominant in the singlet. Effects compete. Until last spring, the common lore was that PDF effects would smear any peak!

Precise mass measurement? Width measurement?

$$V(r) \simeq -C_{[1,8]} \frac{\alpha_s(1/r)}{r}$$

$$C^{[1]} = C_F = 4/3$$

$$C^{[8]} = C_F - C_A/2 = -1/6$$

[Hagiwara et al 2008; Kiyo et al., 2008]

New resonances

In many scenarios for EWSB new resonances show up, some of which preferably couple to 3rd generation quarks.

Given the large number of models, in this case is more efficient to adopt a “model independent” search and try to get as much information as possible on the quantum numbers and coupling of the resonance.

New resonances

In many scenarios for EWSB new resonances show up, some of which preferably couple to 3rd generation quarks.

Given the large number of models, in this case is more efficient to adopt a “model independent” search and try to get as much information as possible on the quantum numbers and coupling of the resonance.

To access the spin of the intermediate resonance spin correlations should be measured.

It therefore mandatory for such cases to have MC samples where spin correlations are kept and the full matrix element $\langle pp | X | tt \rangle$ is used.

Zoology of new resonances

Spin	Color	(I, Y_5) [L,R]	SM-interf	Example
0	0	(1,0)	no	Scalar
	0	(0,1)	no	PseudoScalar
	0	(0,1)	yes	Boso-phobic
	8	(0,1),(1,0)	no	Techni-pi0[8]
1	0	[sm,sm]	yes/no	Z'
	0	(1,0),(0,1)(1,1),(1,-1)	yes	vector
	8	(1,0)	yes	coloron/kk-gluon
	8	(0,1)	“yes”	axigluon
2	0	--	yes	kk-graviton

Phase I: discovery

* Vector resonance, in a color singlet or octet states.

* Widths and rates very different

* Interference effects with SM $t\bar{t}$ production not always negligible

* Direct information on $\sigma \cdot \text{Br}$ and Γ .

Phase I: discovery

Non-trivial behavior (peak-dip) due to the interference between the signal and the background, only if top width dominated by $\phi \rightarrow t\bar{t}$. [Dicus, Stange & Willenbrock 1994]

Single-top

Process	Diagram	Accuracy	CTEQ6M, $m_t=172$ GeV, th err $\approx 10\%$ σ (pb)	
			TeV II	LHC
t-channel		NLO Stelzer, Sullivan, Willenbrock '97	1.98	247
s-channel		(N)NLO Smith, Willenbrock '96	0.88	10.7
tW		NLO Campbell, Tramontano '05	0.07	66

All signals available in MCFM [Campbell, et al.] and in MC@NLO [Frixione et al.]. Most of the backgrounds are also known at NLO. However, analysis still rely on LO calculations for the heavy-quark fractions in W +jets events (largest background)

⇒ room for improvement.

A closer look at single top

t channel

SM info

Largest rate, dominant at the LHC, where 62% top, 38% anti-top.

$$\sigma \propto |V_{tb}|^2.$$

Forward jet in final state, top central, sometimes one extra forward bottom. FB asymmetric at the Tevatron. Main background $W+Q's+jet$ (and tt at the LHC).

Top is polarized along spectator jet (most of the times) in the $2 \rightarrow 2$ configuration.

BSM window

Sensitive to new production modes, through FCNC ($qc \rightarrow qt$).

Associated Higgs production in SUSY.

s channel

SM info

Smallest at the LHC, where 63% top, 37% anti-top.

$$\sigma \propto |V_{tb}|^2.$$

Very well known. DY might be used for normalization.

Central high-pt b-jet. Main backgrounds: tt , tj , and $W+Q's+jets$.

Top is polarized along beam axis at the Tevatron.

BSM window

Sensitive to vector (extra W) and scalar (top pions) resonances.

Spin correlations to study the handedness of the couplings.

Tait
and
Yuan, '00

tW and tH^+

Interest: V_{tb} measurement

The Cinderella of the three channels. Not studied as much as s and t . Tiny at the Tevatron, sizeable at the LHC. It is similar to tt : it just has one b -jet less!

Possible interesting signature: 2 leptons, missing E_t , and **exactly** one b -jet. A b -jet veto is needed for a meaningful definition even at the TH level.

Focus on V_{tb} .

Important background when tt + jet veto is large (Ex: $gg \rightarrow H \rightarrow WW$).

Interest: Charged Higgs discovery

When $m_{H^+} > m_t$, no overlap with tt production, no TH need for a b -jet veto.

When $m_{H^+} < m_t$, tt production, with $t \rightarrow H^+b$ dominates. Overlap with $gb \rightarrow tH^+$ does not create a problem for discovery.

Need to be careful in the transition region $m_{H^+} \sim m_t$.

Example: Relaxing the unitarity constraint in single top analyses

Current analyses at Tevatron assume Standard Model.
 With more data independent direct limits on V_{td}, V_{ts}, V_{tb} are possible.

$$\sigma_{1b\text{-tag}} = R \left\{ \sum_{q=d,s,b} |V_{tq}|^2 \sigma_q^{t\text{-ch}} + 2 (|V_{td}|^2 + |V_{ts}|^2) \sigma^{s\text{-ch}} \right\}$$

$$\sigma_{2b\text{-tag}} = R |V_{tb}|^2 \sigma^{s\text{-ch}}.$$

Conclusions

- Top physics is rich and exciting
- Top is the perfect lab where to test our understanding of EW and QCD.
- Top offers also one of the most promising windows on New Physics
- Room for new ideas both at the theoretical and experimental level and new collaborations!

and if you really become crazy about Top...

TOP QUARK

t

Discovered at Fermilab in 1995, the **TOP QUARK** is as short-lived as it is massive. Weighing in at a hefty 175 GeV, its lifetime, a mere 10^{-24} second, is the briefest of the six quarks. Top Quarks are an enigmatic particle whose personal life is sought after by thousands of physicists.

Acrylic felt with gravel fill for maximum mass.
