

# RG scaling at chiral phase transition in two-flavor QCD

K.-I. Ishikawa(Hiroshima U.)

Y. Iwasaki(U. Tsukuba)

Yu Nakayama(CalTech)

T. Yoshie(U. Tsukuba)

## Objective

Clarify the nature of the chiral phase transition for  $N_f=2$   
first order or second order ?

If second order, estimate critical exponents

## Strategy

derive new RG scaling relations

verify whether the scaling is satisfied for data  
on lattice with  $N_s = 16, 24, 32$

## Results

the data excellently satisfy the scaling relations

It implies the transition is second order

the anomalous mass dimension  $0.67 \sim 1.1$

# Stage and Tools

SU(3) gauge theories with degenerate two quarks

Action: RG improved gauge action + Wilson fermion action

Lattice size:  $32^3 \times 16$ ,  $24^3 \times 12$ ,  $16^3 \times 8$

Boundary conditions: periodic boundary conditions except for an anti-periodic boundary conditions in the t direction for fermions

Algorithm: Blocked HMC for 2N and RHMC for 1 :  $N_f = 2N + 1$

Statistics: 1,000 +1,000 ~5000 trajectories

Computers: U. Tsukuba: CCS HA-PACS; KEK: SR16000

# Chiral phase transition

- $\beta_c \approx 2.8$ ;  $K_c = 0.1455$  on the  $32^3 \times 16$  lattice;
- $\beta_c \approx 2.6$ ;  $K_c = 0.149$  on the  $24^3 \times 12$  lattice;
- $\beta_c \approx 2.3$ ;  $K_c = 0.1547$  on the  $16^3 \times 8$  lattice.

estimated by “on  $K_c$  method”,

monitoring the number of iteration of CG inversion

From the results of spectroscopy on  $16^3 \times 64$  lattice we obtain

$$T_c \sim 163 (+11; -1) \text{ MeV}$$

# RG equations

At the vicinity of a critical point where the correlation length becomes infinity, the following RG equations hold.  
note: **only relevant operators** included

Temporal propagator

$$G_t(nt; g, mq, N_s, N_t, \mu) = \left(\frac{N'}{N}\right)^{-2\gamma} G_t(nt'; g', m'q, N_s', N_t', \mu').$$

Spatial propagator

$$G_s(ns; g, mq, N_s, N_t, \mu) = \left(\frac{N'}{N}\right)^{-2\gamma} G_s(ns'; g', m'q, N_s', N_t', \mu')$$

may use  $r = N_s/N_t$        $N = N_t$

# Scaling at IR fixed point

$$g=g'=g^*; m_q=m_q'=0;$$

Temporal propagator

$$G_t(n_t; g^*, m_q=0, N, \mu) = \left(\frac{N'}{N}\right)^{3-2\gamma} G_t(n_t'; g^*, m_q'=0, N', \mu).$$

$$G_t(\tau, N) = \left(\frac{N'}{N}\right)^{3-2\gamma} G_t(\tau, N'). \quad \tau = n_t/N$$

effective mass

$$m(n_t, N) = \ln \frac{G(n_t, N)}{G(n_t + 1, N)}$$

scaled  
effective mass

$$\mathfrak{m}(n_t, N) = N m(n_t, N)$$

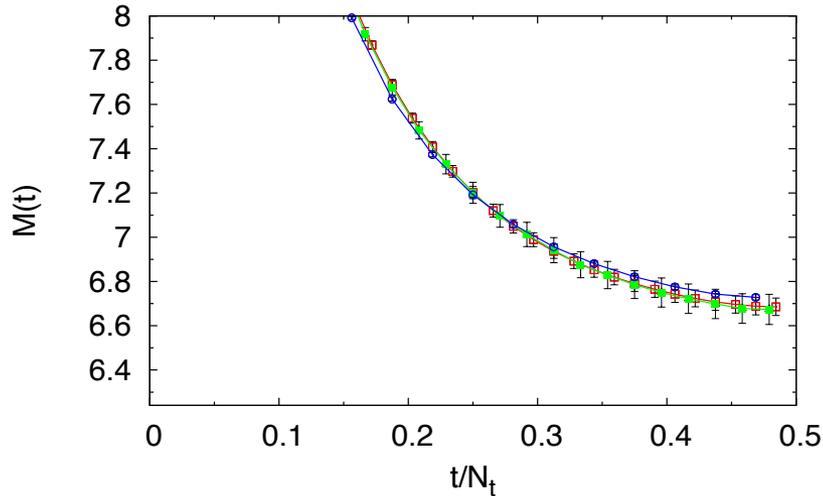

$$\mathfrak{m}(\tau, N) = -\partial_\tau \ln \tilde{G}(\tau, N)$$

# Scaling at IR fixed point

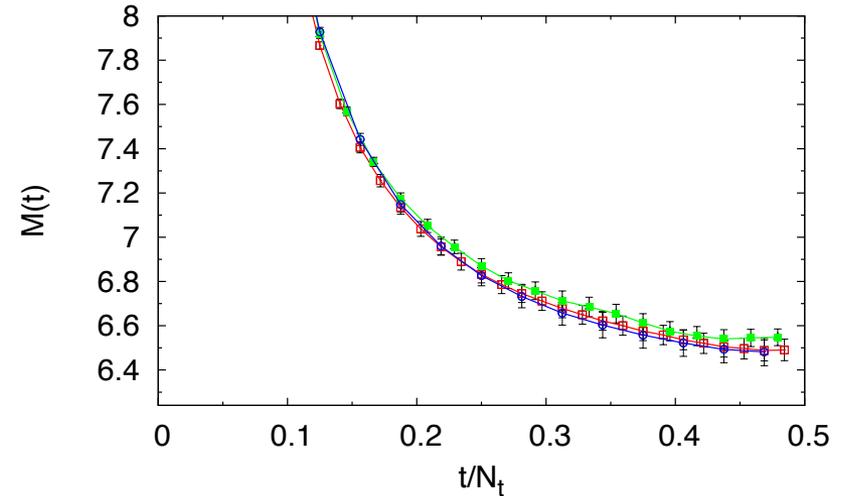

$$m(\tau, N) = m(\tau, N')$$

Phys.Lett.B 748 (2015) 289;arXiv: 1503.02359

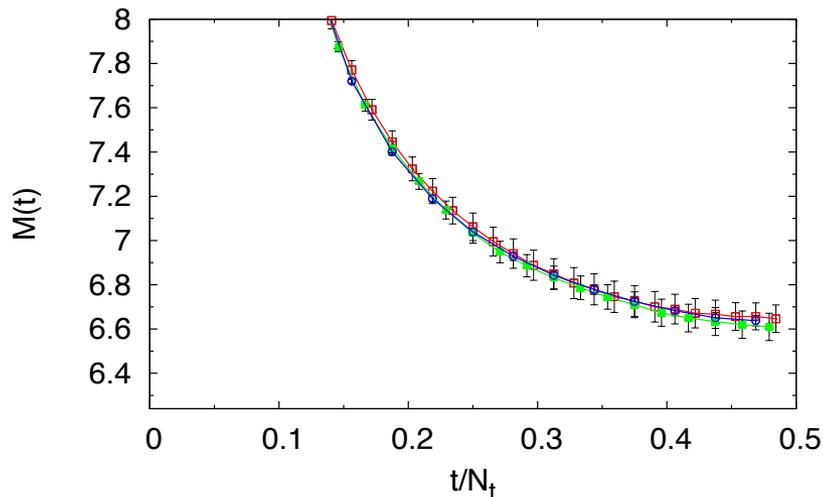

Effective mass: Nf=16; beta=10.5, K=0.1292

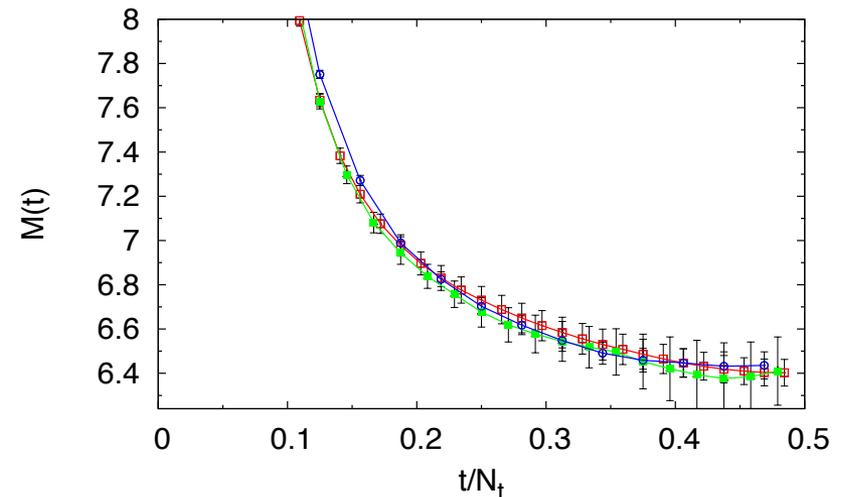

Effective mass: Nf=08; beta=2.4, K=0.147

Effective mass: Nf=12; beta=3.0, K=0.1405

Effective mass: Nf=07; beta=2.3, K=0.14877

# SCALING AT CHIRAL PHASE TRANSITION

temporal  $\mathbf{m}_t(\tau, g, N) = \mathbf{m}_t(\tau, g', N')$

spatial  $\mathbf{m}_s(\tau, g, N) = \mathbf{m}_s(\tau, g', N')$

Numerical data scale

the data excellently scale both for the spatial and temporal effective masses, in the pseudo-scalar and vector channel, respectively, except only for short distance at  $n=0, 1, 2$

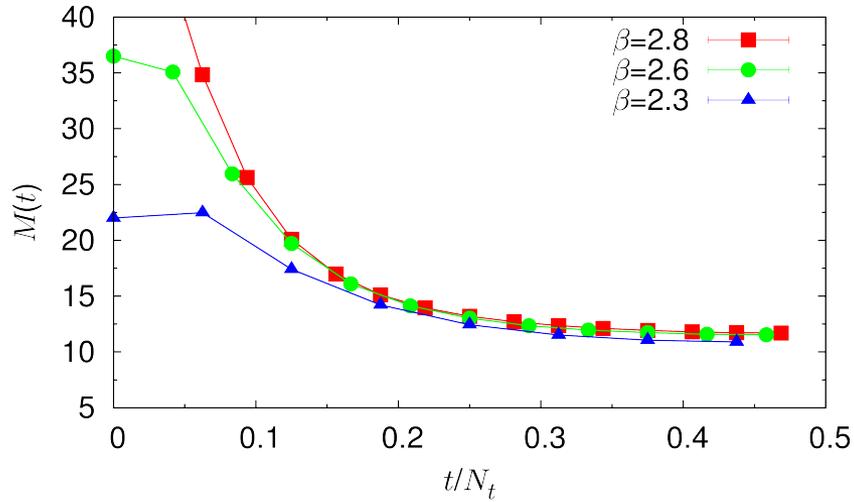

scaling curves give continuum limit

beta function is common both to spatial and temporal effective masses

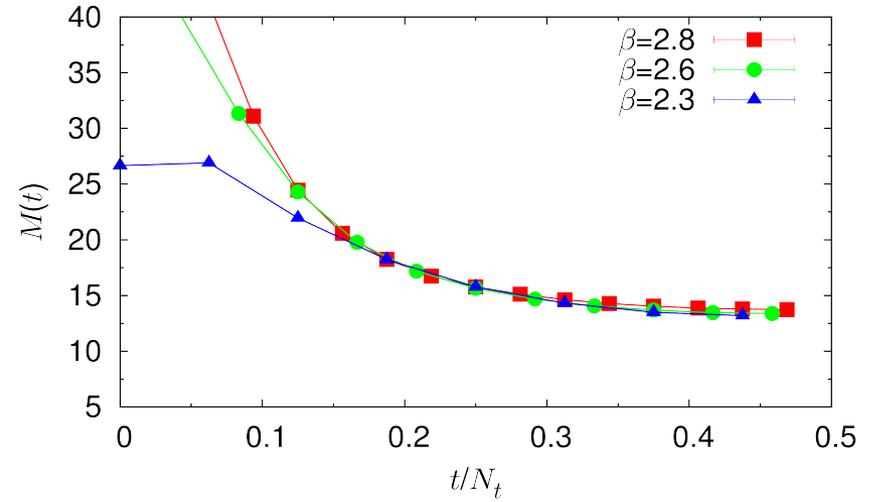

# Numerical data scale

spatial

PS: effective mass:  $\beta=2.8, 2.6$  and  $2.3$

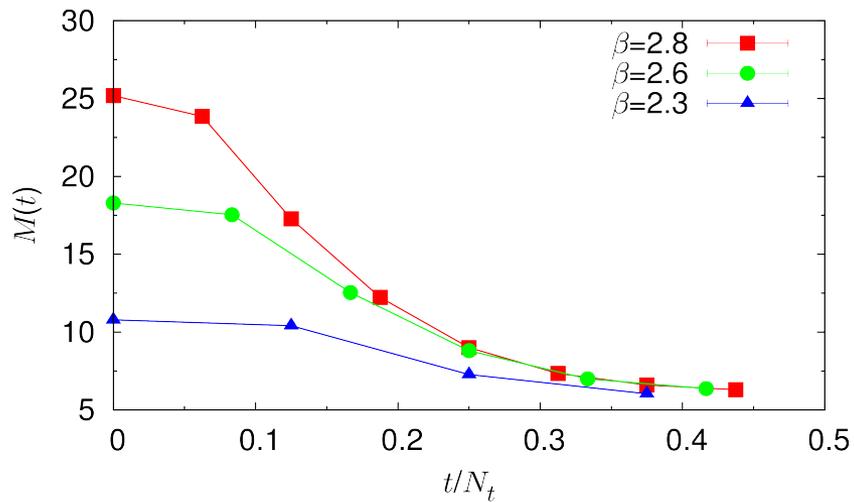

V: effective mass:  $\beta=2.8, 2.6$  and  $2.3$

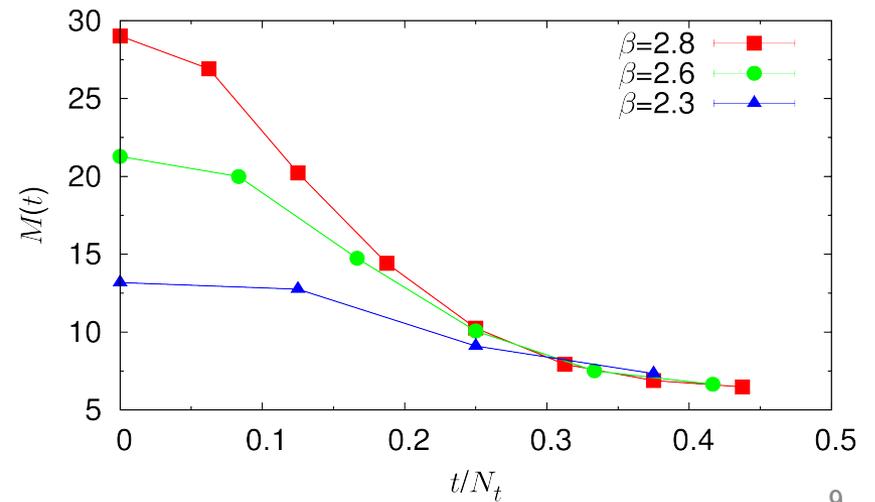

temporal

t-PS: effective mass:  $\beta=2.8, 2.6$  and  $2.3$

t-V: effective mass:  $\beta=2.8, 2.6$  and  $2.3$

# Scaling and Continuum limit

Scaling implies

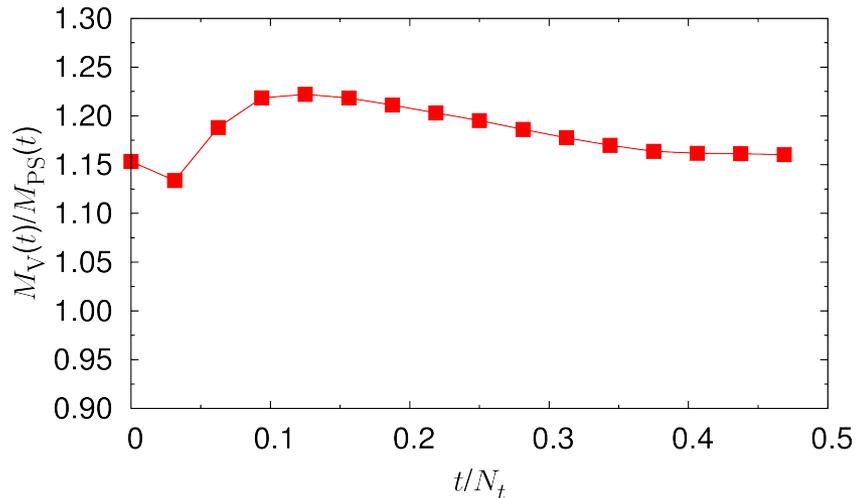

$$m_s(\tau, g, N) = \mathfrak{F}_s(\tau)$$

independent from g and N

**this is the continuum limit**

ratio of vector to pseudo-scalar

Effective Mass Ratio V/PS

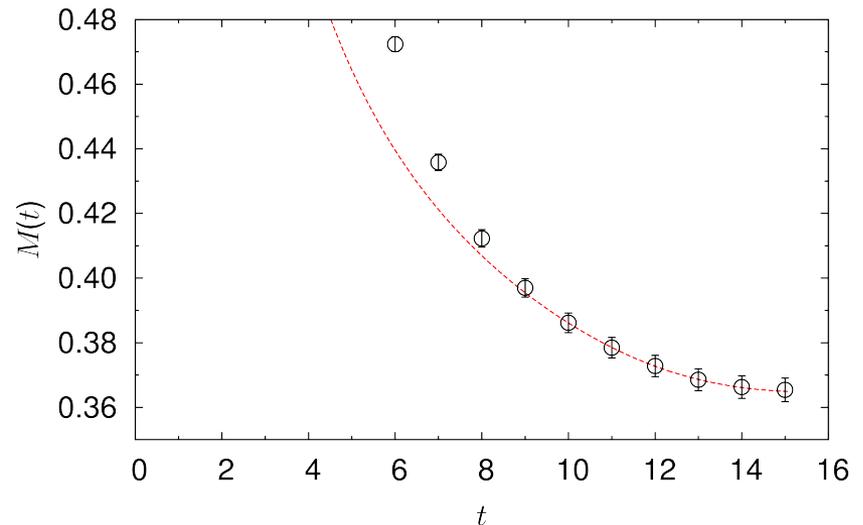

Effective mass decay with a power modified Yukawa type

an example below

fit  $m=0.305(7)$

power=0.87(6)

effective mass enlarged:  $32^3 \times 16$ ,  $\beta=2.8$ ,  $K=0.1455$

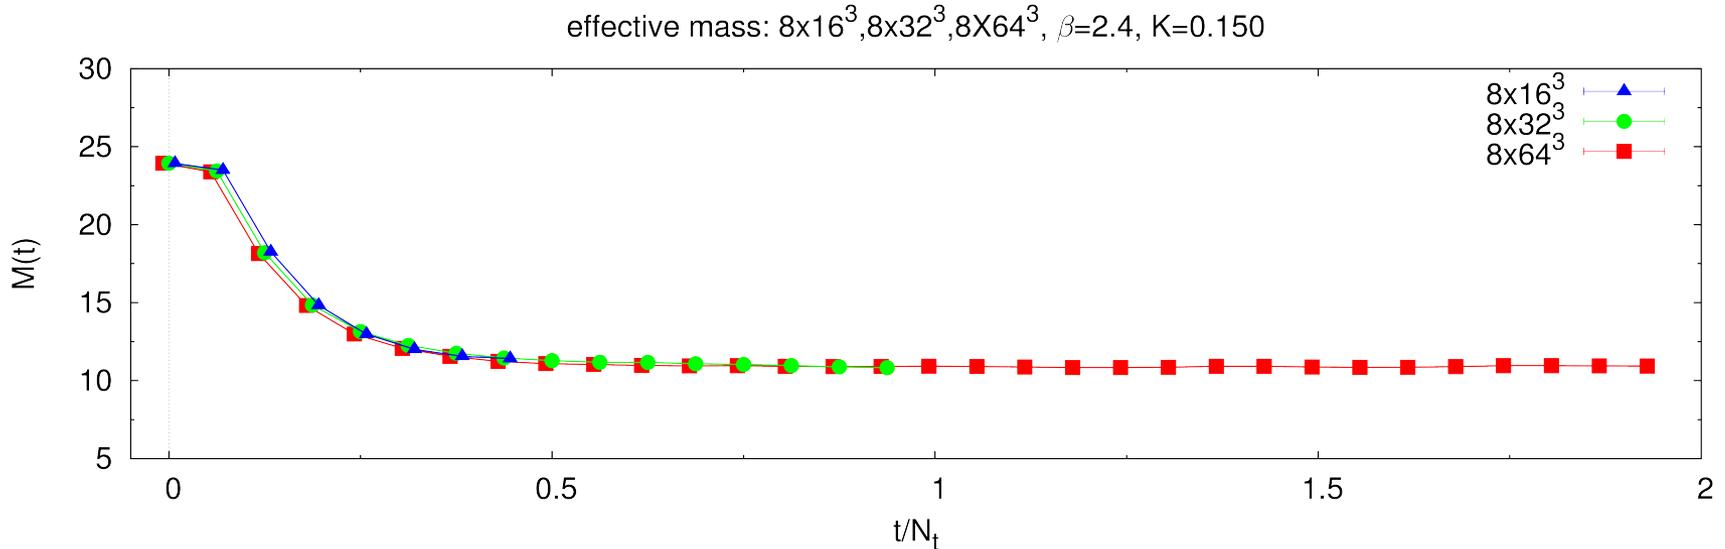

# Thermodynamic Limit

Effective mass decay with a power modified Yukawa type

$$G(\tau) = A \exp(-m \tau) / \tau^\alpha$$

$$m(\tau; N_x) \simeq \hat{m} + \alpha/\tau \quad \hat{m} : \text{thermodynamic limit}$$

Increasing volume, modified Yukawa type as shown does not change

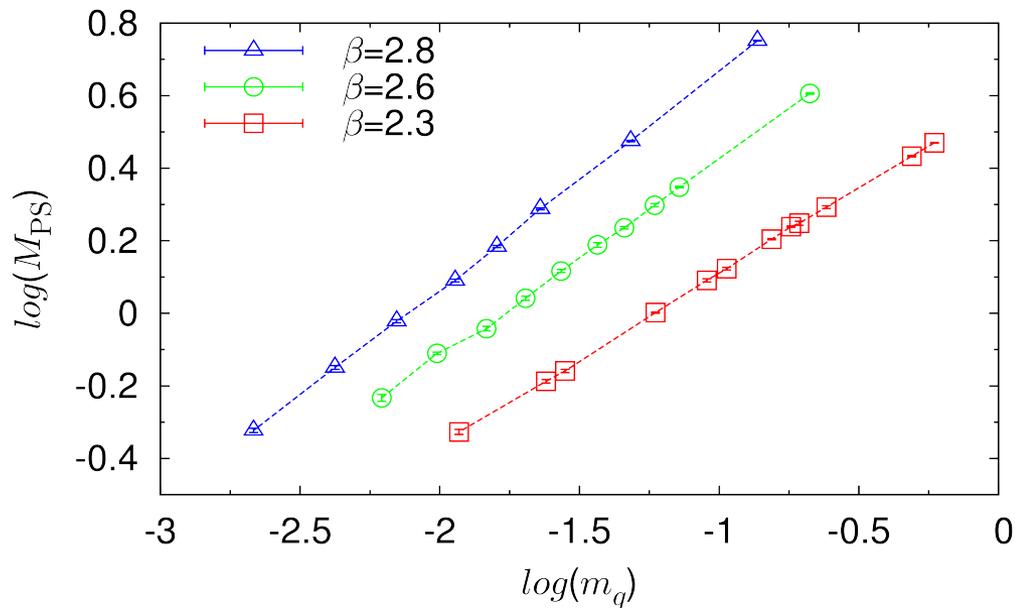

# Hyper Scaling relations and anomalous mass dimension

Fit  $\ln m_\pi = \alpha \ln m_q + c$

$$m_\pi = m_q^{1/1+\gamma^*}$$

$$\gamma^* = 1/\alpha - 1$$

log-log plot  $m_q$  VS  $M_{\text{PS}}$ :  $\beta=2.8, 2.6, 2.3$

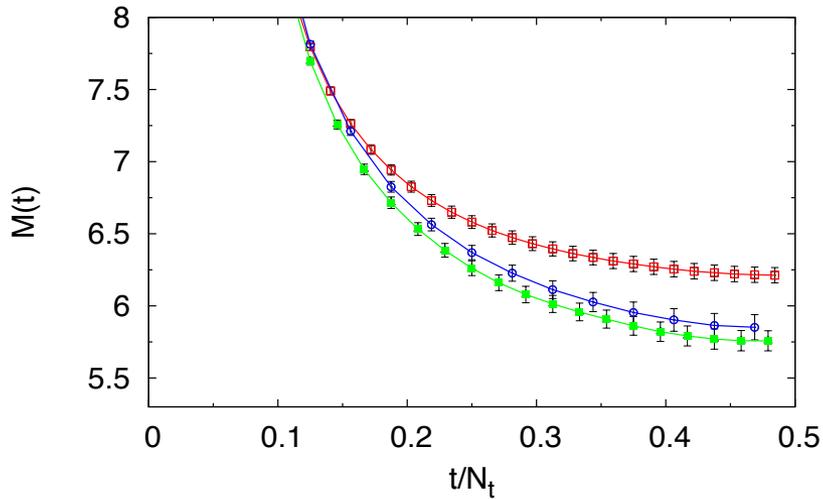

$\beta$	$\alpha$	$\gamma^*$
2.3	0.468(1)	1.14(4)
2.6	0.545(2)	0.83 (7)
2.8	0.600(2)	0.667(6)

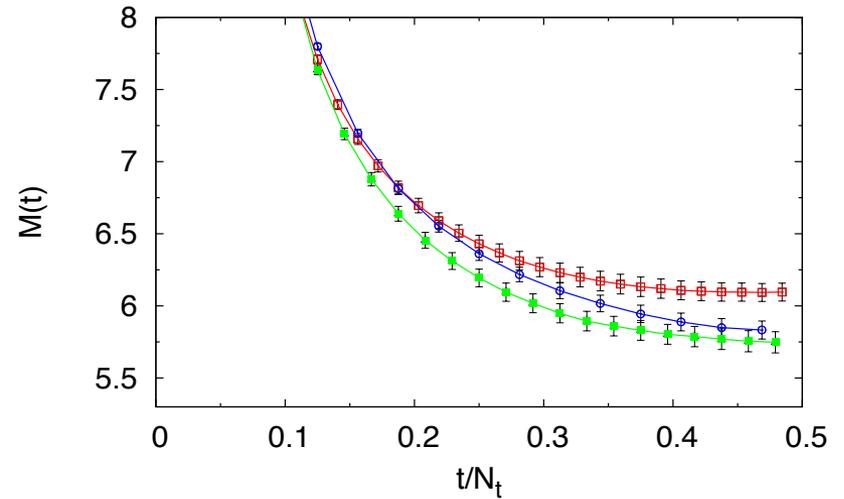

at each lattice the hyper scaling relation excellently is satisfied  
 However, the anomalous mass dimension does not scale well.

# Search a critical point on lattices with $r=1/4$

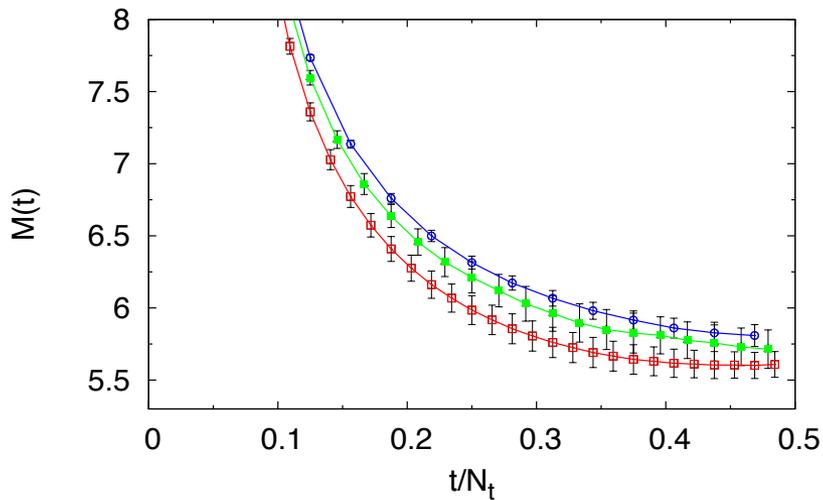

Effective mass:  $N_f=02$ ;  $\beta=7.0$ ,  $K=0.144$

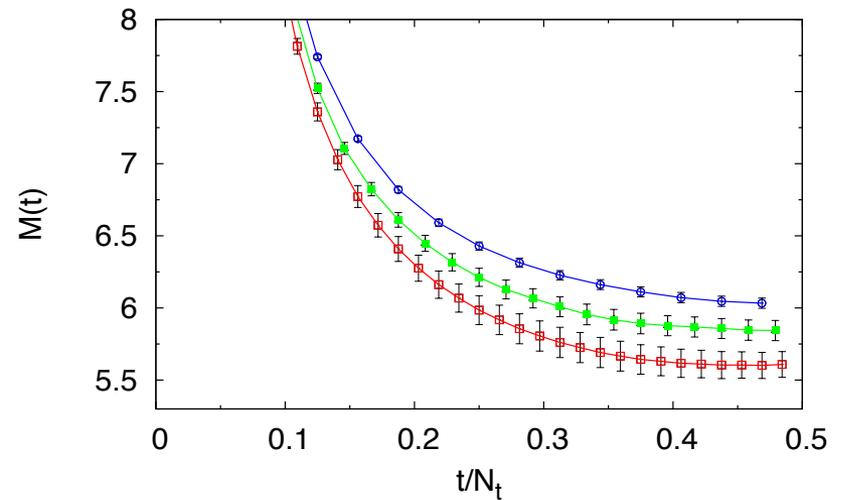

Effective mass:  $N_f=02$ ;  $\beta=6.9$ ,  $K=0.146$

Effective mass:  $N_f=02$ ;  $\beta=6.7$ ,  $K=0.146$

Effective mass:  $N_f=02$ ;  $\beta=6.6$ ,  $K=0.147$

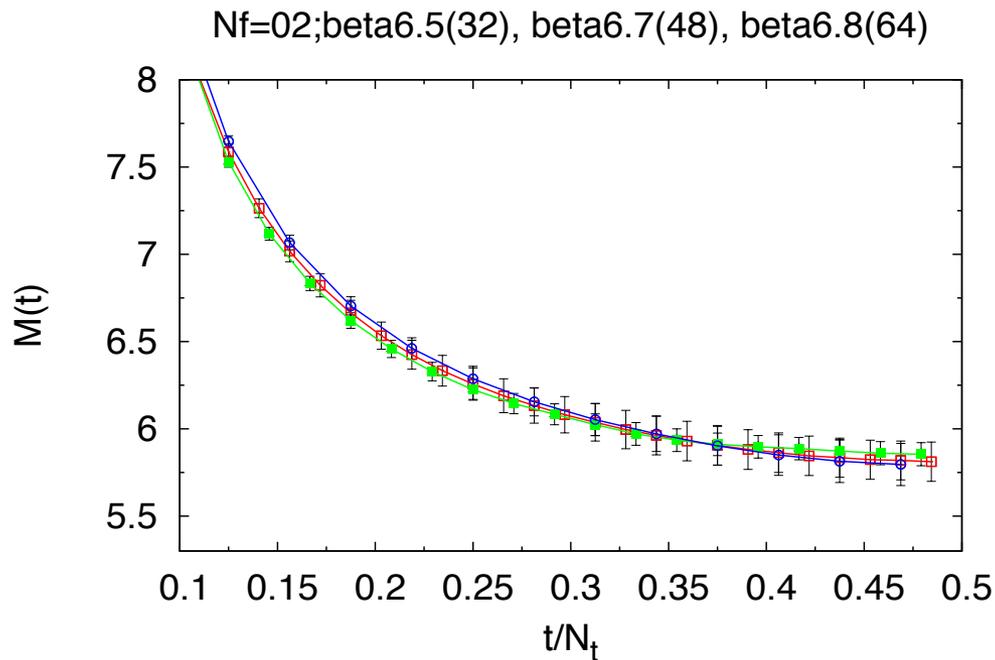

# Search a critical point on lattices with $r=1/4$

Action = one plaquette gauge action

Size =  $16^3 \times 64$ ,  $12^3 \times 48$ ,  $8^3 \times 32$

data at  $\beta=6.8$  on  $16^3 \times 64$ ,  $\beta=6.7$  on  $12^3 \times 48$ ,  $\beta=6.5$  on  $8^3 \times 32$   
scale  $\Rightarrow$  critical point (preliminary)

# Summary and Discussion

Wilson's basic idea:

in the vicinity of a critical point RG equations are satisfied

Usually it is considered that a critical point is an IR fixed point

Scaling relation at an IR fixed point

$$m(\tau, N) = m(\tau, N')$$

If the chiral phase transition is second order, it is a critical point

Numerical data excellently satisfy RG scaling relations

$$m_t(\tau, g, N) = m_t(\tau, g', N') \quad m_s(\tau, g, N) = m_s(\tau, g', N')$$

It implies the chiral transition is second order

may suppress  $g$ , since  $T$  and aspect ratio  $r$  given,  $g(a)$  are fixed

$$m_s(\tau, N) = m_s(\tau, N') \quad m_s(\tau, N) = m_s(\tau, N')$$

The same form as the scaling at IR fixed point

They imply "scale invariance"
