### What is an axion, A?

Hypotethical elementary particle, leading candidate for dark matter.

### What is the mass of the axion, $m_A$ ?

Related to the topological susceptibility of QCD

$$m_A^2 = \chi/f_A^2, ext{ where } \chi = \langle Q^2 
angle/V$$

### What is the scale of the axion, $f_A$ ?

Axions are produced during the evolution of the early Universe. Density depends on  $f_A$ : the larger the  $f_A$  the more axions are produced. Determine  $f_A$  from

$$\rho_{A} = \rho_{\rm dark\ matter}$$

## Lattice QCD

# Calculate the density of axions produced in the early Universe!

expansion of the universe  $\rightarrow$  Equation of State ( $\rightarrow$  see next-to-next talk) evolution of the axion field  $\rightarrow$  Topological Susceptibility

## The challenges

1. Very few tunneling for large temperatures and/or fine lattices

2. Very large lattice artefacts.

## Fixed sector integral

See also Frison, Kitano, Matsufuru, Mori, Yamada 1606.07175.

Instead of waiting for tunneling events, we make simulations in fixed Q sectors. Howto get

 $Z_1/Z_0 = ?$ 

First calculate **derivative** of  $\log Z_1/Z_0$ :

$$b_1(T) \equiv \frac{d \log Z_1/Z_0}{d \log T}$$

Use fixed  $N_t$ -approach, ie.  $T = (aN_t)^{-1}$  is changed by  $\beta$ :

$$b_1(T) = rac{deta}{d\log a} \left( \langle S_g 
angle_1 - \langle S_g 
angle_0 
ight)$$

**Integration** gives the relative ratio:

$$|Z_1/Z_0|_{\mathcal{T}} = \exp\left(\int_{\mathcal{T}_0}^{\mathcal{T}} d\log \mathcal{T}' \ b_1(\mathcal{T}')\right) Z_1/Z_0|_{\mathcal{T}_0}$$

Start from a temperature  $T_0$ , where standard approach is feasible.

**Remark:** *b*<sub>1</sub> is directly related to the **fall-off exponent**:

$$b(T) = \frac{d \log \chi}{d \log T} \simeq b_1(T) - 4$$

(For high temperatures, where only Q = 0 and 1 are contributing  $\langle Q^2 \rangle \simeq \frac{2Z_1}{Z_0 N_t N_s^2 a^4}$ )

## Fixed Q integral - quenched

Fixed Q simulation: extra acc/rej step at the end of each update, as lattice spacing decreased the acceptance gets better.

Test in quenched case: pure Wilson action upto  $7 \cdot T_c$  and  $8 \times 64^3$ 

standard method: extrapolation using a fit; integral method; Dilute Instanton Gas Approximation: exponent agrees nicely, but order of magnitude difference in  $\chi$ 

ロト ・ ア・ ・ ヨト ・ ヨト

## Fixed Q integral - fermions

Lattice spacing is changed by  $\beta$  and quark masses  $m_f$ :

$$b_1(T) = \frac{d \log Z_1/Z_0}{d \log a} =$$
$$= \frac{d\beta}{d \log a} \langle S_g \rangle_{1-0} + \sum_f \frac{d \log m_f}{d \log a} m_f \langle \overline{\psi} \psi_f \rangle_{1-0}$$

### **Remarks:**

- 1. Very large cutoff effects on  $\langle \overline{\psi}\psi\rangle$  ( $\rightarrow$  see next talk).
- 2. Gauge action part is much noiser, than the fermion part.

## Simulation strategy

Evaluate susceptibility and decay exponent at a quark mass, where the simulation is less expensive than at phys. point. Three flavor symmetric point.

Carry out an integration in light quark mass from  $m_s$  to  $m_{ud}$ .

**The fall-off exponent** agrees with DIGA/SB limit for temperatures above  $T \sim 1$ GeV, for smaller *T*'s somewhat smaller.

The susceptibility is considerably larger than the DIGA prediction.

Equation of State and Topological Susceptibility.

They give an axion mass of  $m_A = 50(4) \ \mu eV$  (in post-inflation with same amount of topological defects as misalignement).
