Physics involving muons @ ATLAS/LHC

Standard Model Higgs

The signal for Higgs boson must be extracted from a background several order of magnitude higher.
The channels experimentally cleaner are the ones having leptons in the final states

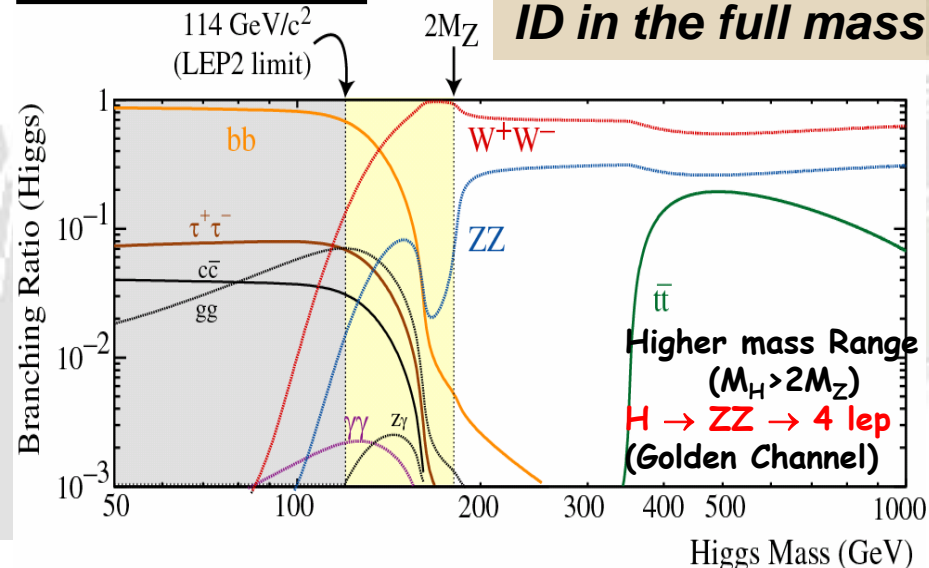

Many different signatures in this mass region:

- more relevant are
- $H \rightarrow \gamma\gamma$ $\sigma \times BR \sim 45$ fb (LO for $M_H = 130$ GeV)
- $H \rightarrow 4l$
- e.g. $H \rightarrow ZZ^*$ $\sigma \times BR \sim 1$ pb (LO for $M_H = 130$ GeV)

Intermediate Range
($130 < M_H < 2M_Z$)
 $H \rightarrow WW^* \rightarrow lnl$
 $H \rightarrow ZZ^* \rightarrow 4 lep$

Muons are fundamental for trigger and signature ID in the full mass range

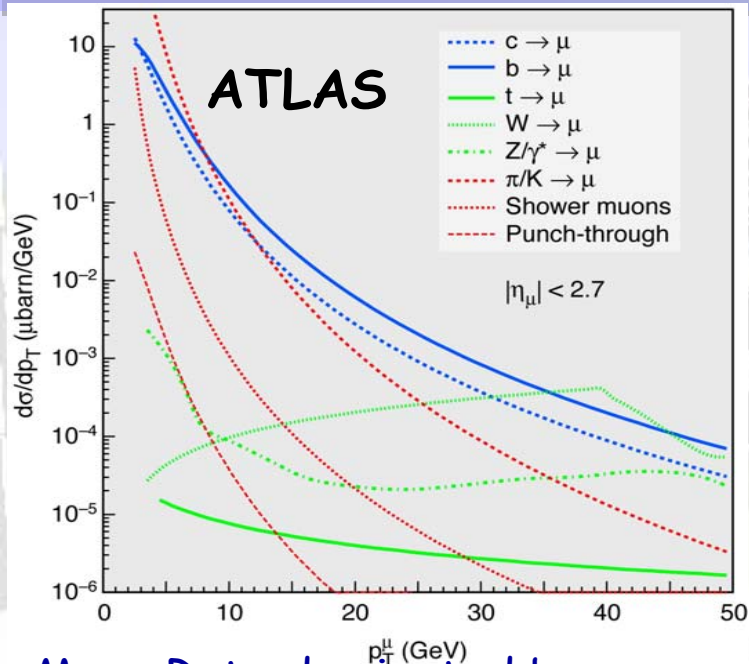

$A/H \rightarrow \mu\mu$:

- covers good part of region not excluded by LEP
- can be discovered even at very large masses
- experimentally easier than $A/H \rightarrow \tau\tau$,
 - this compensates the reduced rate
- relevant for mass and couplings measurement

crucial point: reconstruct high- p_T muons from narrow resonance $\rightarrow 5\sigma$ sensitivity reachable in 1 year ($10fb^{-1}$) @low luminosity ($10^{33}cm^{-2}s^{-1}$)

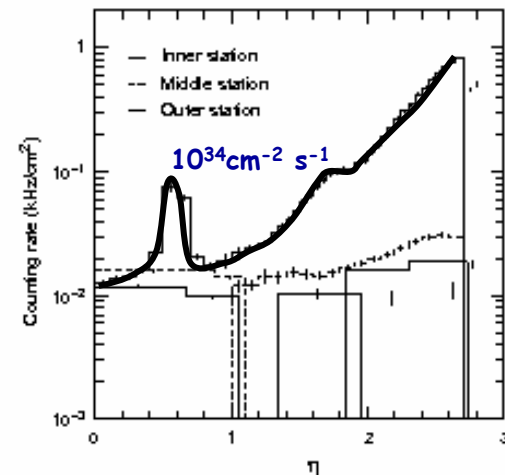

Muon rates and Background

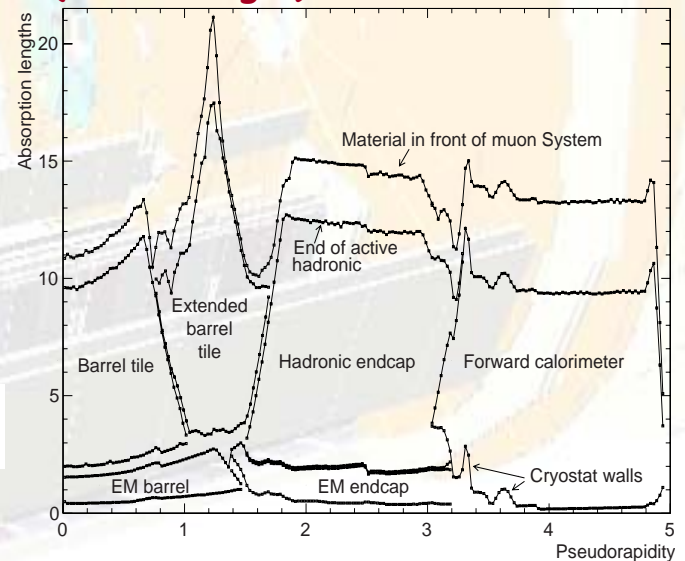

Particles produced in the interactions of primary hadrons from p-p collisions with the material of the Detector. The result of these interactions is mainly the production of neutrons that diffuse throughout the hall producing secondary particles when interacting with matter.

A Gas of Photons ($E < 1$ MeV) and low energy Neutrons ($E < 100$ KeV) is the main source of uncorrelated background in the MS (cavern bkgr.)

Muon Rate dominated by: b,c,light mesons and W decays

total counting rates, obtained by multiplying the background rates with the detector efficiencies, as a function of η

Single counting rate (ATLAS, high Lum.):
Barrel < 40 Hz/cm²
End Cap 20-1000 Hz/cm²

Muon Identification systems in ATLAS Detector

□ When a charged particle(μ) moves through a detector it leaves a set of hits in the Inner Detector(ID) and in the MuonSpectrometer(MS). A hit provides information about the track parameters at the measurement location.

□ The reconstruction goal is to find the track associated to the hits and perform a fit in order to obtain the better estimate of the trajectory parameters describing the particle.

•MS:

B toroidal (inhomogeneous) ~ 0.5 T

$\Rightarrow p_T$: with high p_T

\Rightarrow Problems for low p_T

\Rightarrow Muon(μ) Identification

•Calorimeters:

Loss of energy

(sometimes catastrophic)

Fluctuations of E_{loss}

Electromagnetic showers

•ID:

Solenoid $B \sim 2$ T

\Rightarrow Precise measurements

at low p_T , but muon

Identification is needed

➤ Why Pattern Recognition?

There are several sources of hits: Tracks from interaction in LHC, coming from different bunch crossing, cosmic particles, electronic noise, Radioactivity

➤ **The pattern recognition main task** is to properly associate hits to particle trajectories in order to find the full set of track parameters by searching for the best fit of a physically valid track.

ATLAS Muon Spectrometer

- Barrel divided in 16 ϕ sectors (small(S) and large(L))
- **3 air-core** (to minimize multiple scattering) superconducting toroids: 1 barrel (BT) + 2 End Caps toroids (ECT) → **track curvature in r-z plane.**
- **bending of the muons:**
 - $|\eta| < 1$ for toroid of the **barrel**
 - $1.4 < |\eta| < 2.7$ from the magnets of the **endcap**
 - $1.0 < |\eta| < 1.4$ in the **transition region.** This Radial Overlap of the BT and ECT fields *ensures the widest acceptance for single muons*
- **Equipped with trigger and precision chambers(4 technologies)**
 - Trigger selectivity: threshold $p_T > 6\text{GeV}/c$ for b-physics and $p_T > 20\text{GeV}/c$ for high momentum particle
 - **Low p_T muons** ⊗ ID and Tile calorimeter (for these momenta p_T resolution is dominated by inner tracker ⊗ **for B physics the MS is primarily used as a Level 1 muon trigger or to validate the muon candidate and match it with inner tracker**)
 - Second coordinate measurement (in the non bending plane) for reliable momentum determination.
- **The final aim is to reach the highest efficiency with standalone momentum resolution of a few % level at 10-100 GeV/c and ~10% at 1 TeV/c**

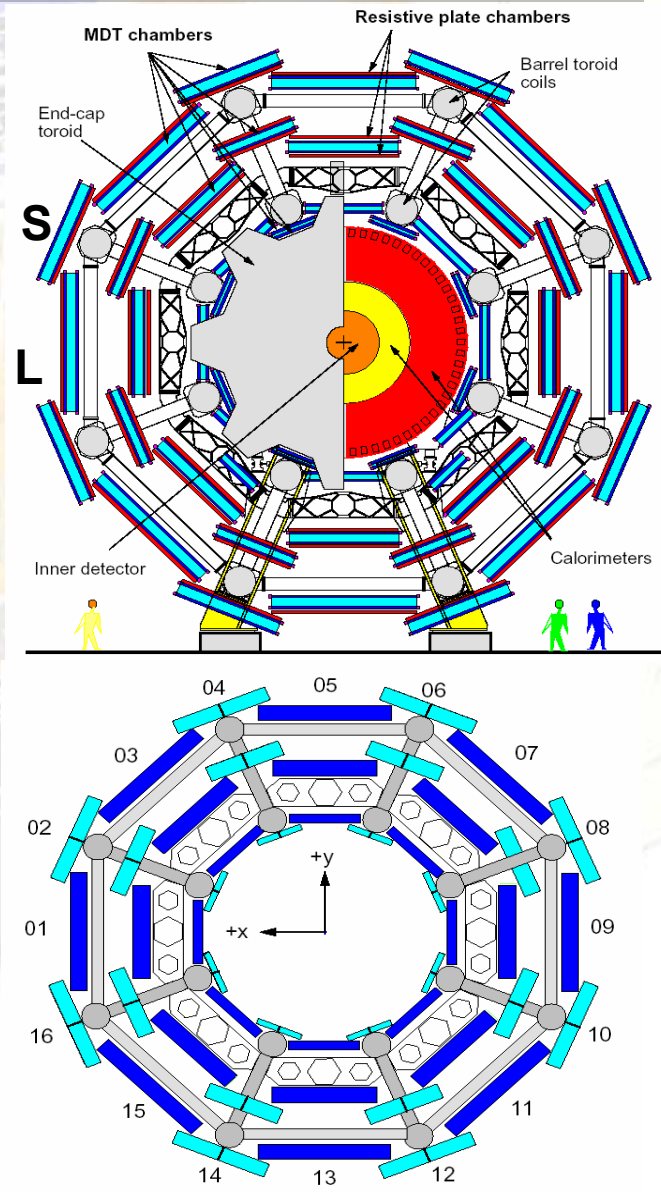

Figure 3-5 Definition of sectors; view into +z direction

Precision Muon Chambers

Precision measurement in the bending direction of the Magnetic Field (MF)

□ MDTs (Monitored Drift Chambers)

- The basic elements are **drift tubes** with a diameter of 3 cm and a variable length from 70 cm to 630 cm
- The tubes are organized in multi-layers of 3
 - (4 for inner stations)
- single wire average spatial resolution $\approx 80 \mu\text{m}$

□ CSCs (Cathode Strip Chambers)

- Placed in the inner ring of the endcap region, $2 < |\eta| < 2.7$ where a high density of tracks is to be expected
- MWPC with readout on the segmented cathode strips perpendicular to the anode wires
- Spatial resolution $\approx 60 \mu\text{m}$, small drift time (30 ns), good time resolution $\approx 7 \text{ ns}$
- Transversal coordinate measurement is given by cathodical strips parallel to anode wires

Muon Trigger chambers

Muon trigger chambers are used in ATLAS for selecting bunch crossings containing interesting interactions (μ trigger), and for measuring the second coordinate (ϕ). The *trigger* system cover the $|\eta| < 2.4$ region.

Barrel RPCs (Resistive Plate Chambers): on both sides of MDT in the “middle” stations and directly above or immediately below the “outer” stations .

Endcap TGCs (Thin Gap Chambers) : 3 stations close to MDT “middle” stations. MWPC (with wires parallels to MDTs) and read-out strips perpendicular to the second coordinate measurement.

Time resolution ≈ 1 ns
Space resolution in $\phi \approx 1$ cm

Very short drift time due to the thin gap \rightarrow **good time resolution needed for Bunch Crossing ID**
Wire (\parallel to the MDT wires) signal used to provide the trigger, strip (\perp to the wires) signals used for the second coordinate

Fine granularity is needed since trigger chambers are outside B and will have a short lever arm

Measuring muons in MS Barrel sector

- ✚ Precision measurements of z in the bending direction of the MF ($\sigma_z=80\mu\text{m}$) with 3 MDT stations
- ✚ MDT station: 2 multilayers of 3 (4 in the inner station) layers of monitored drift tubes
- ✚ Trigger and measurements of $z-\phi$ coord. ($\sigma_{z\phi} \sim 1\text{cm}$) with 2 RPC layers in the middle station + 1 RPC layer in the outer station
- ✚ RPC layer: 2 gas gaps read independently

Total: ~ 20 precision z measurements +
~ 6 $z-\phi$ measurements

Measuring muons in MS Endcap sector

$|\eta| < 2.0$

□ Precision measurements of r ($\sigma = 80\mu\text{m}$) with 3 MDT stations with 2 multilayers of 3 (4 in the inner station) layers of tubes

2 × 3 MDT layers

Trigger and measurements of $r-\phi$ ($\sigma_\phi \sim 1\text{cm}$) with:
 2 double-gap TGC layers
 1 triple-gap TGC layer
 1 double-gap TGC layer in the innermost station (only measur.)

2 × 4 MDT layers

Total: ~ 20 precision r measurements +
 ~ 9 $r-\phi$ measurements

$2.0 < |\eta| < 2.7$

□ Precision measurements of r with:
 □ 4 CSC layers ($\sigma = 60\mu\text{m}$) +
 □ 2 MDT stations with 2 multilayers of 3 layers of tubes +
 □ 4 ϕ measurements (CSC ϕ strips, $\sigma_\phi < 1\text{cm}$)

Total: ~ 16 precision r measurements +
 ~ 7 $r-\phi$ + 4 ϕ measurements

Trigger and measurements of $r-\phi$ with 3 outermost TGC stations

ATLAS Muon Magnet System

BT: $|\eta| < 1$

- 26 m long
- Internal/External radii: 9.5m/20m
- 8 separate coils, 1 cryostat per coil
- bending power $\int Bdl = 2-6 \text{ Tm}$

ECTs: $1.4 < |\eta| < 2.7$

- Inserted into the BT edges, 8 coils per ECT, rotated of 22.5° with respect to BT coils
- 5 m long
- Internal/External radii: 1.7m/10.7m
- 1 cryostat per ECT
- bending power $\int Bdl = 4-8 \text{ Tm}$

ECT $\rightarrow p_T$ resolution constant up to $|\eta| < 2.7$

BT Open structure \rightarrow allows for chambers installed inside and for alignment optical corridors to cross it

Long barrel+short EC \rightarrow minimize magnetic forces and costs

B field measured with 5000 Hall probes but global calibration of the energy scale is needed

Field integral inhomogeneous in the tracking volume

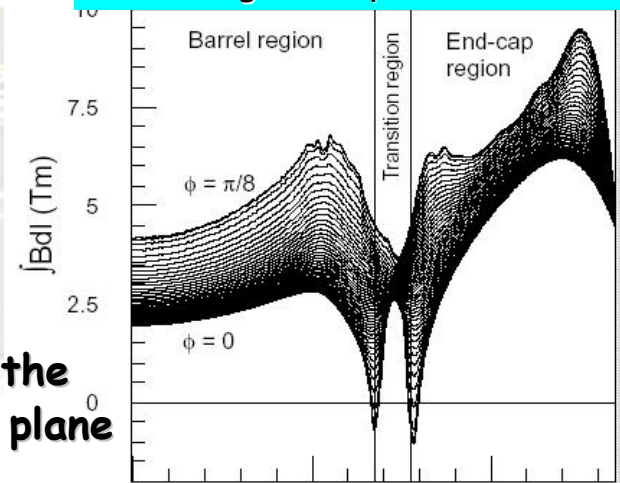

Need to measure accurately the coordinate in the non bending plane

Need to take into account the differences in Lorentz angle for the calibration of the tracking chambers

Barrel toroid Detector Feet Rails EC toroid

Field integral vs η for radial tracks

Muon Reconstruction principles

- ❑ precise, but very distant local measurements
- ❑ field very inhomogeneous
- ❑ material, to be taken into account
- ❑ "noise"
- ❑ **RPC: strips in η and ϕ (cm)**
 - ❑ areas of activity in which one will seek the segments

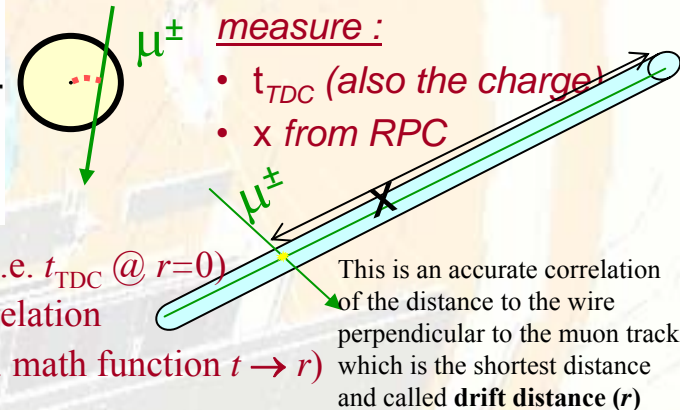

Drift time + RT = ring ($80\mu\text{m}$)
 Segment = tangent with all these rings

BUT

- ❑ zone ineffective (center, edge)
- ❑ "noise", "Dead time" ($\sim 700\text{ns}$ ~ Rayon tubes)

t_0 and r/t relation

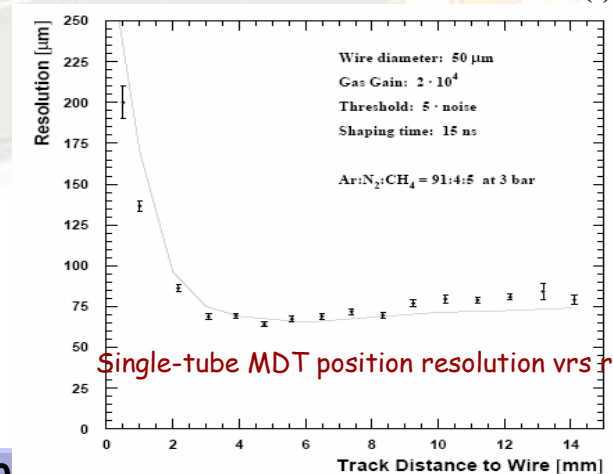

From a Precision Digit to a Precision Hit

The creation of an MDT hit starts by subtracting from the digits drift time, the time it takes to the signal for propagating along the tube-wire to the front-end electronics.

The MDT chambers do not measure the azimuthal coordinate along the wire, so to determine this propagation time, the overlap region of the wire with the trigger chambers ϕ measurements is used together with a signal-speed. The time is then corrected for the tof from the interaction point to the MDT tube. **The resulting drift time is subsequently converted to a distance and a correction for the Lorentz angle is applied.**

The $r-t$ relation is used to obtain a position measurement from the time measurements.

StandAlone (SA) Muon Reconstruction

- Fast identification of “regions of activity” in the muon detector guided by the trigger chambers where exist an intersection of η and ϕ strips.
- Reconstruction of local straight track segments in the bending plane in each station:
 - drift distance calculation from R-T relation
 - corrections for time propagation along the wire by using the 2nd-coord. from RPC and TGC and for Lorentz angle
 - linear fit
- Combinations of compatible segments in the same MDT station and in different stations to identify track candidates.
- These segments are combined if they are close in direction
- Track fit:
 - takes into account multiple scattering and energy loss in the MS inert materials
 - track parameters and the relative covariance matrix are given at the first measured point inside the MS

❑ Track extrapolation back to the interaction region:

- ❑ takes into account multiple scattering (parametrized by means of scattering planes in the Calos) and
- ❑ energy loss in the calorimeters (as a function of (η, p))
- ❑ track re-fit and new parameters at the interaction vertex

■ Track parameters:

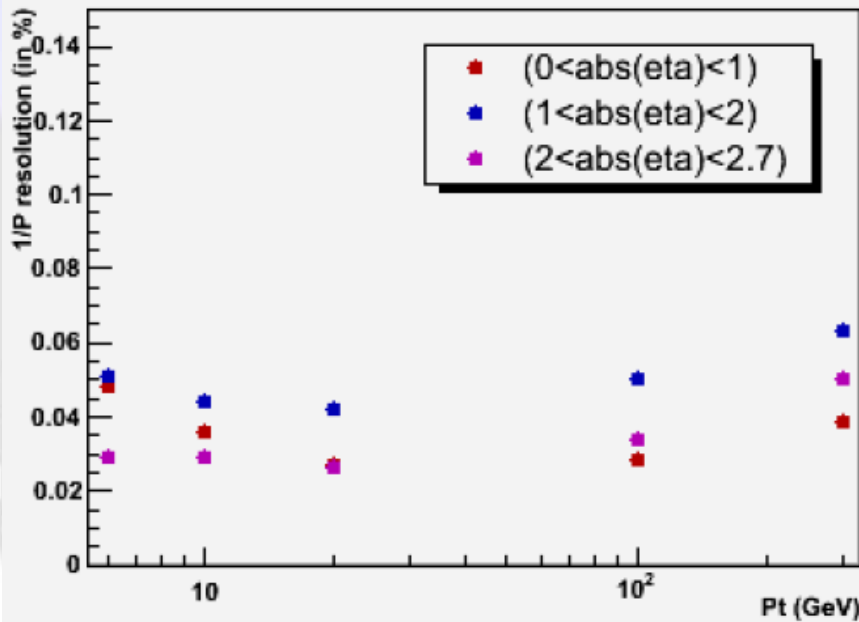

- a_0 : the transverse impact parameter.
- z_0 : the longitudinal impact parameter.
- Φ : the azimuthal angle $\Phi = p_y/p_x$
- $\cot(\theta)$: cotangent of the polar angle $\cot(\theta) = p_z/p_T$
- $1/p_T$: reciprocal of the transverse momentum. It is signed according to the charge of the particle.

p_T resolutions

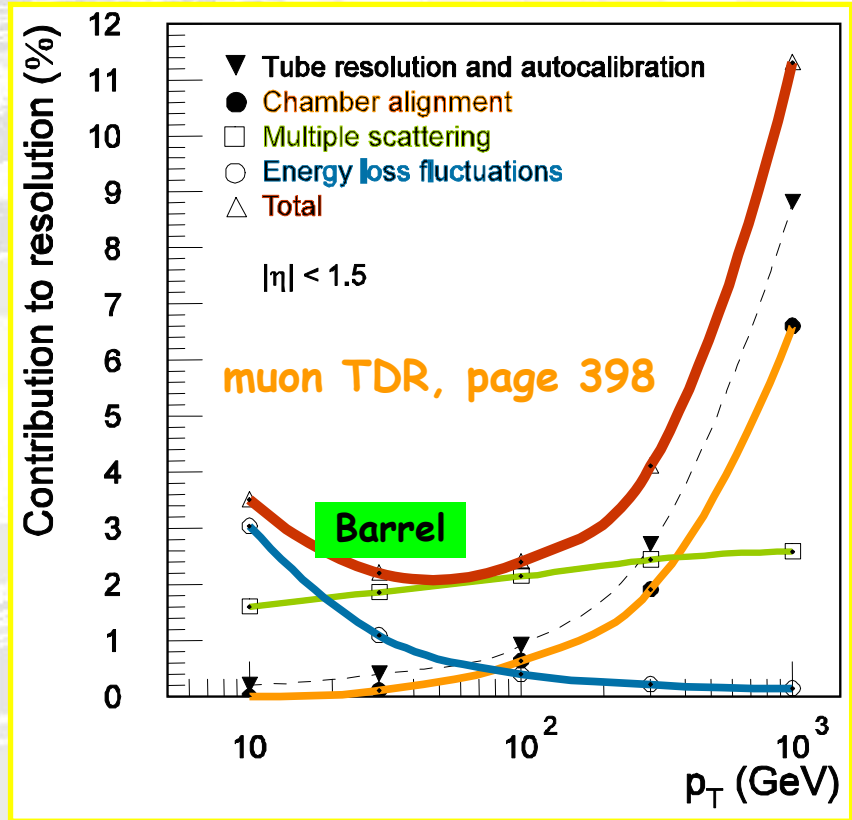

The muon spectrometer resolution dominates for $P_T > 100 \text{ GeV}/c$

Resolution limited by :

- Mult.Scatt. and Energy Loss Fluct. for $P_T < 30 \text{ GeV}/c$
- Mult.Scatt. for $30 < P_T < 300 \text{ GeV}/c$
- Chamber Resolution, calibration and alignment for $P_T > 300 \text{ GeV}$

$\Delta p_T/p_T = 0.1$ @ $p_T = 1 \text{ TeV}/c$
 $p_T = 1 \text{ TeV}/c \rightarrow 500 \mu\text{m}$ sagitta;
 $\Delta s = 50 \mu\text{m}$

- Chamber Spatial Resolution (per point) $\sim 80 \mu\text{m}$
- Accurate calibration: time-to-distance relation within $\sim 20 \mu\text{m}$
- Wire positioning inside tracking chambers within $\sim 20 \mu\text{m}$
- CSC strip $\sim 100 \mu\text{m}$ for $|\eta| > 2$
- Chamber Alignment within $\sim 30\text{-}40 \mu\text{m}$ (barrel - endcaps)
- Magnetic field knowledge @ few permille

Desired p_T Resolution

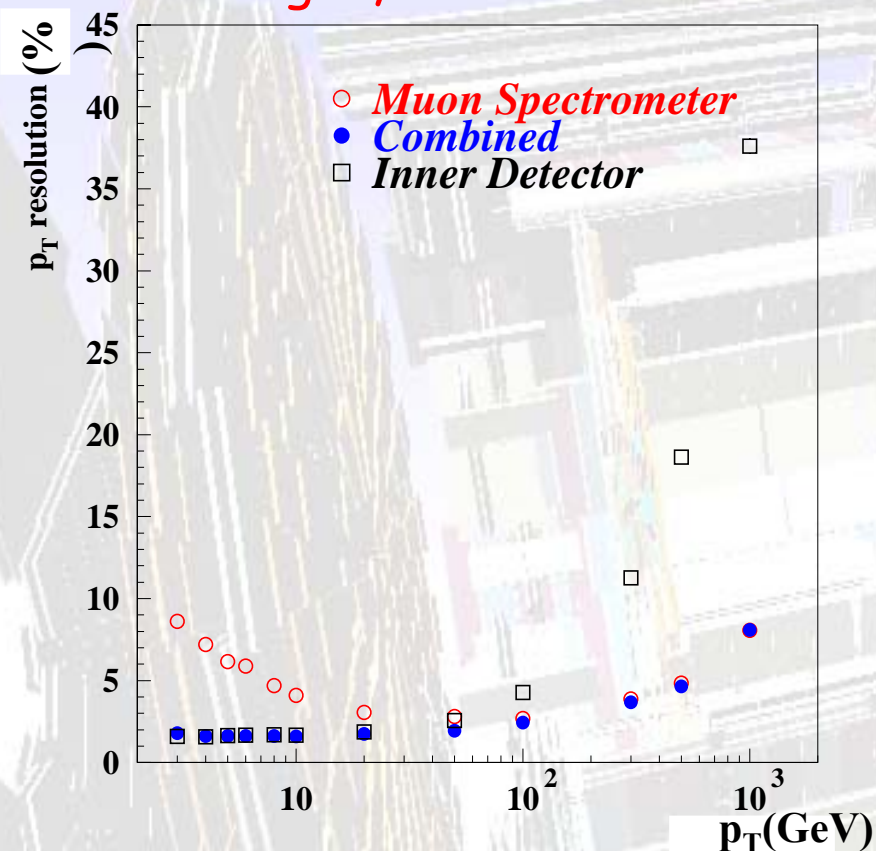

H, Susy, b, t, W $p_T < 100 \text{ GeV}$ $\delta p_T/p_T \sim 2\%$
 Exotics, W' $p_T \sim 1 \text{ TeV}$ $\delta p_T/p_T \sim 10\%$

Why Combined Reconstruction (I)

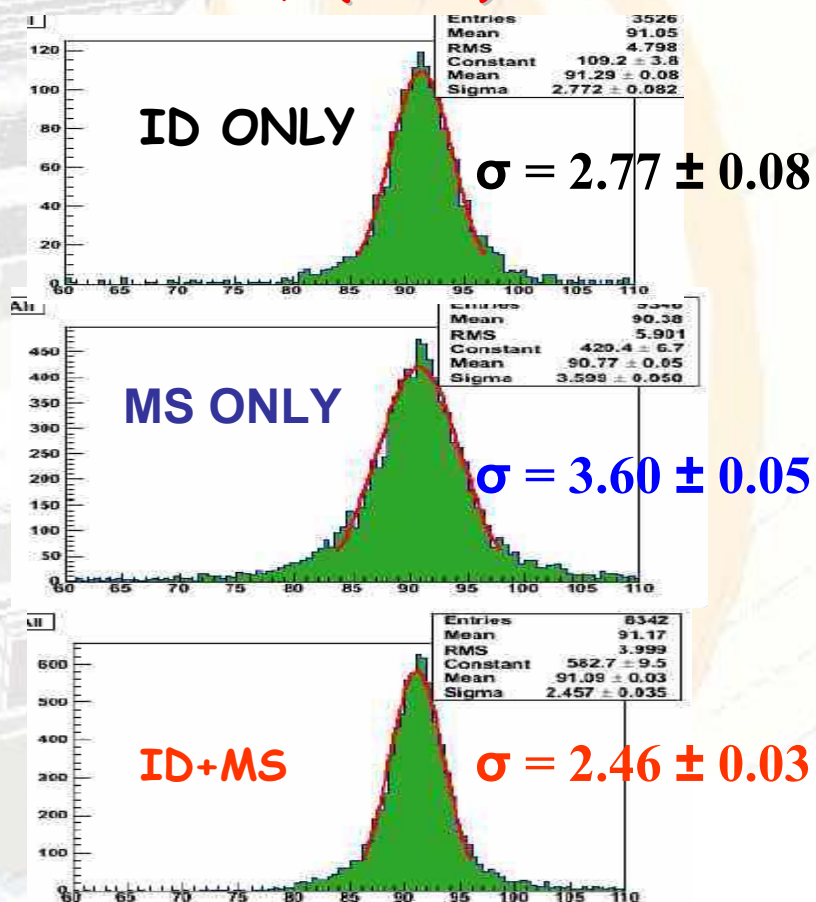

- ✚ **Improves the parameters measured by the track**
 - ✚ Allows a better momentum resolution
 - ✚ $20 \text{ GeV} < p_T < 100 \text{ GeV}$
 - ✚ Reduces the tails in the muon spectrometer resolution, mainly related to fluctuations in the calorimeters energy deposition
- ✚ **Improves Muon Identification**
 - ✚ Reduction of fakes reconstruction, particularly in presence of cavern background
 - ✚ Reconstruction of low p_T muons that do not reach all the spectrometer stations
 - ✚ Rejection of μ coming from K, π decay requiring that the tracks are generated at the vertex
 - ✚ Discrimination of muon in hadronic jet from hadrons. A good μ identification for non isolated muons is needed for an efficient b-tagging.
- ✚ **Allows a better understanding of the experimental apparatus**
 - ✚ Test of calorimeter calibration
 - ✚ Cross check for Inner Detector and spectrometer results

Why Combined Reconstruction (II)

Single μ

$Z \rightarrow 2\mu$ (DC3)

Improvement in momentum resolution

$20 \text{ GeV} < p_T < 100 \text{ GeV}$

- Improvement of $\sigma(Z_{\text{mass}})$ by $\sim 10\%$ ($\sim 30\%$) compared to ID (MS)

pT resolution: variation with pT and η

■ $(\Delta p_T/p_T)$ is sum of measurement component (increases with pT) and Coulomb scattering component (constant)

■ Inner Detector

Resolution in extended barrel region ($\eta < 1.9$)

Measurement: $\sim 40\% * p_T$ (TeV)

Scattering: $\sim 1.5\%$ constant term

Rising to $200\% * p_T + 3\%$ at $\eta = 2.5$ (acceptance limit) as track exits solenoid with smaller traversed radial length Resolution approximately Gaussian

■ Muon Spectrometer

In barrel and endcap toroids

Measurement: $\sim 10\% * p_T$ (TeV)

Scattering: 2~3% in barrel

3~4% for $\eta > 1.8$

Scattering dominates for p_T below ~ 300 GeV

$\sim 150X_0$ material traversed \Rightarrow non-Gaussian tails when back-tracked to vertex region

■ Inner Detector more precise at low momenta

■ barrel toroid region : for p_T below 40~80 GeV

■ at substantially higher p_T for toroid transition region ($1.2 < \eta < 1.8$)

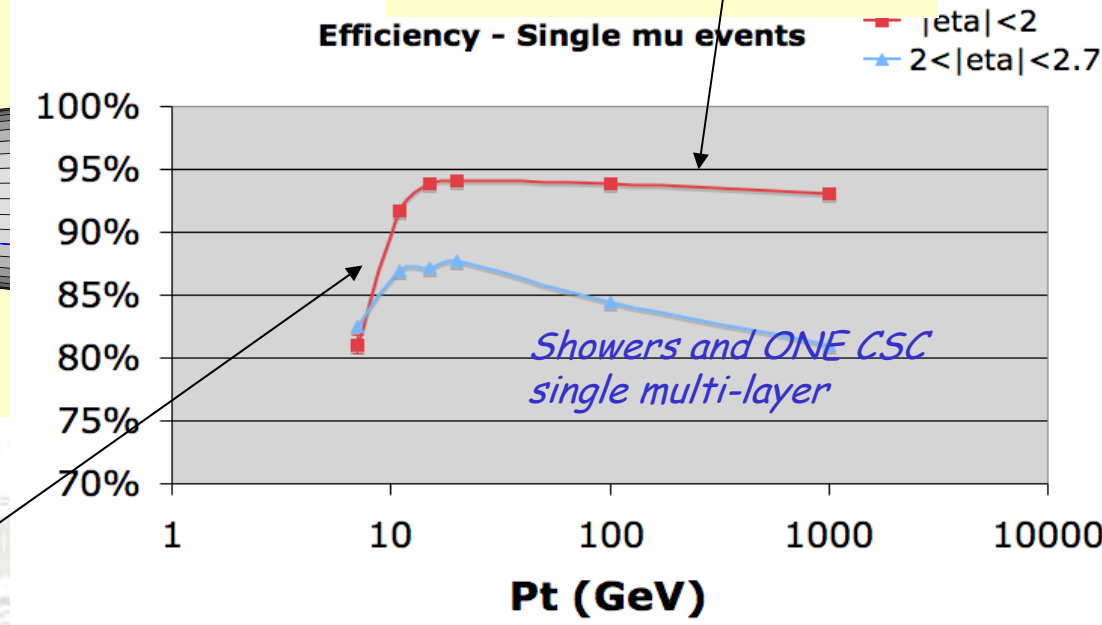

■ endcap toroid region

■ cross-over at ~ 80 GeV at $\eta \sim 1.8$

■ falls with increasing η to below 20 GeV at InDet acceptance limit $\eta = 2.5$)

low p_T MuonIdentification

'Drop' : muon showers in Calos

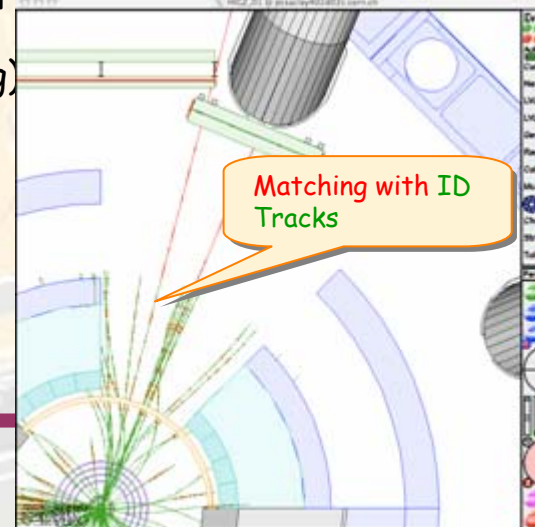

Low Pt algorithms must be used to recover efficiency

- ⚡ **Reconstruction (SA-Combined) efficiency decreases very quickly at low p_T**
- ⚡ Muon reconstruction at low p_T in a very inhomogeneous MF is delicate
 - ⚡ "complicated" trajectories, increased rate of "noisy" tracks
- ⚡ Many μ 's leave the calorimeters with a very weak energy and they don't reach at "medium" or "outer" stations
 - ⚡ large fraction of the E_{loss} in the Calorimeters (3 GeV), at low η

Muon Reconstruction Algorithms

- ❑ **Muonboy** \equiv fully integrated in ATHENA software framework
 - ❑ standalone reconstruction in the MS
- ❑ **STACO** \equiv track extrapolation to the Interaction point (IP) and combined reconstruction with Inner Detector and muon id
 - ❑ Statistical combination of two measurements using the parameters of the reconstructed tracks and their covariance matrixes
 - ❑ works because the ID and Muon System measurements are independent
 - ❑ reminder: propagation down to beam line of the MS track
 - ❑ (accounting for Eloss corrections, multiple scattering)
- ❑ **MuTag** \equiv low pT muon identification
 - ❑ starting from ID reconstructed tracks, at the perigee
 - ❑ Track extrapolation to the inner and middle MS stations
 - ❑ To fill the hole around $\eta \approx 1.3 \rightarrow$ EE chambers are missing
 - ❑ try to associate ID tracks with segments which were not already associated with a combined track (STACO)
 - ❑ apply additional cuts to the quality of the segments
- ❑ **MOORE** \equiv Muon Object Oriented Reconstruction:
- ❑ **MuID** \equiv Muon Identification
- ❑ Global fit of muon tracks by using the hits measured separately by ID and MS with muons at the time of the SA Reconstruction
- ❑ **MuidLowPt**: extrapolated tracks at the MS chambers (MDT, RPC, CSC), and their hits are associated ID-tracks according to their proximity in η and ϕ
 - ❑ Similar reconstruction strategies

- ✦ Fully integrated in the new Reconstruction EDM requirements
- ✦ Modular and Flexible Structure
- ✦ Can be used, integrated and expanded for other applications:
 - ✦ TestBeam, Commissioning, etc..

Reconstruction Output – Event Types

- ❑ **ESD (Event Summary Data)** - This is the output of combined reconstruction
 - ❑ Contains reconstruction output data, at the level of hits on track and calo cells
 - ❑ Calibration, alignment studies, refitting tracks, track extrapolation, analyses
 - ❑ Size ~ 1 Mb / event
- ❑ **AOD (Analysis Object Data)** - This is the reduced event representation output of reconstruction on ESD suitable for most physics analysis.
 - ❑ Contains reconstruction output data, at the level TrackParticles and CaloClusters, very loosely identified particles
 - ❑ the final event data objects used for analysis. - about 100 kB.
- ❑ **TAG** - This is an *event-level meta-data* which is a thumbnail to give efficient identification and selection of events of interest to a given analysis.
 - ❑ Size: ~2 kB per event.

Muons in the ESD/AOD

▶ "high Pt" and "low Pt" algorithms "give" muons which are merged and placed inside a **MuonContainer** (i.e. Data access key : "MuidMuonCollection", "StacoMuonCollection")

▶ [StoregateKeysForESD](#) , [StoregateKeysForAOD](#) , [Muon in the EventTag](#)

▶ The class that stores the muons can be found at: [AOD Muon Class](#)

▶ Below is a list of some of the functions and what they return

▶ [muonEvent](#)

▶ [MuonAnalysisTutorial](#)

Several MC data samples have been used

- Single muon samples for a fixed p_T
 - (from 3 GeV/c up to 1 TeV/c)
- $Z \rightarrow \mu\mu$ (Jimmy)
- $H \rightarrow ZZ^* \rightarrow 4\mu$

MuonSpectrometer Layout

Initial Layout main modifications wrt DC1/2:

- EES and EEL chambers have been removed:
 - performance degradation is expected for $1.0 < \eta < 1.4$
- Half as many CSC chambers (single layer)

missing EE chambers
+ holes in EI coverage

Single muons: efficiency vrs p_T

Single muons, no backg.

Efficiency plateau $\sim 95\%$

Low p_T :

- Only μ with $E > 3-4$ GeV/c reach the MS
- These muons don't reach the MS external station \rightarrow few measurements
- Multiple scattering and inhomogeneous B make the pattern recognition more complicated

High p_T :

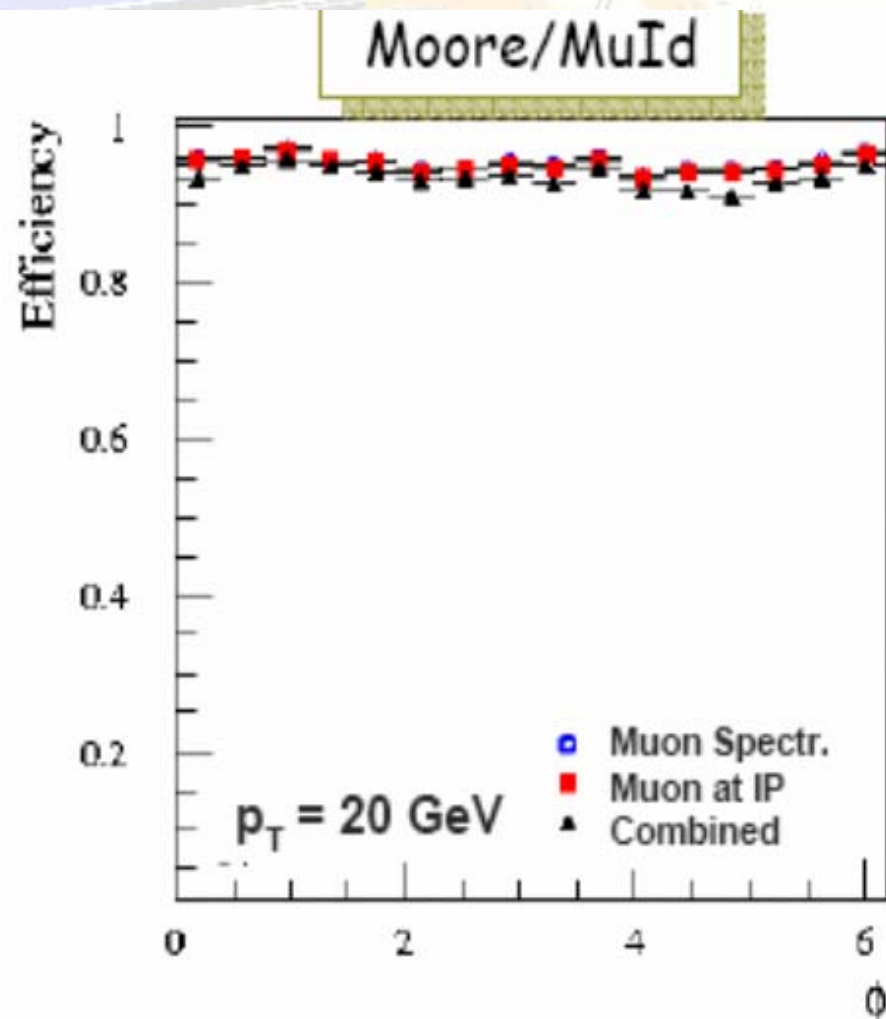

- decreased efficiency of combined reconstruction at very high p_T since pattern recognition suffers of possible e.m. showers accompanying high p_T muons

H(130) $\rightarrow 4\mu$ - Performance plots

Efficiency vs P_t

Single muons : efficiency vrs ϕ

Uniform eff vrs ϕ

Single muons : efficiency vrs η

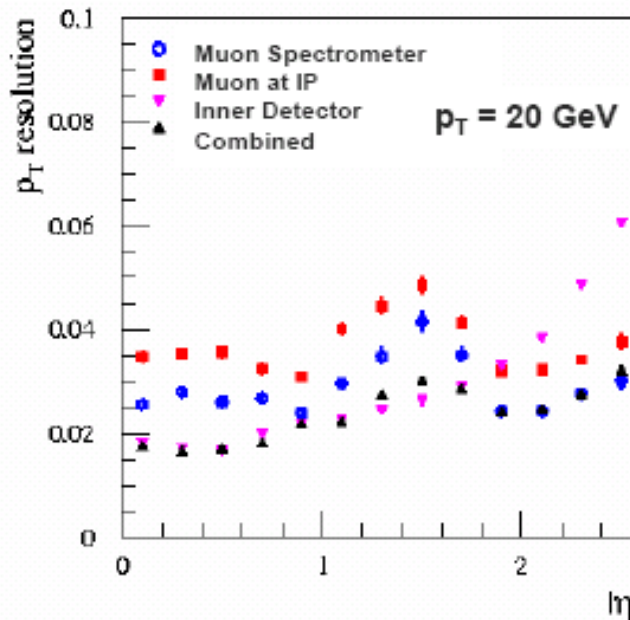

- Low Efficiency at $\eta \approx 0$ due to a central *crack* needed for cables and services (not present in *layout wrt* TDR)
- Second coordinate of CSC missed in the simulation \rightarrow low efficiency for $|\eta| > 2$
- Magnetic field tracking hard in the region $1 < |\eta| < 1.5 \rightarrow$ low efficiency for low $p_T \mu$

Single muons : momentum resolutions

+ Inner Detector dominates below 20 GeV/c
+ MS dominates at high p_T

pT resolution vrs η

Degradation of pT resolution in the transition region caused by a magnetic field highly inhomogeneous and from the fluctuations related to the absorption material in the calorimeters (mainly for μ at low pT)

tracking is complicated in the region $1. < |\eta| < 1.4$ ←

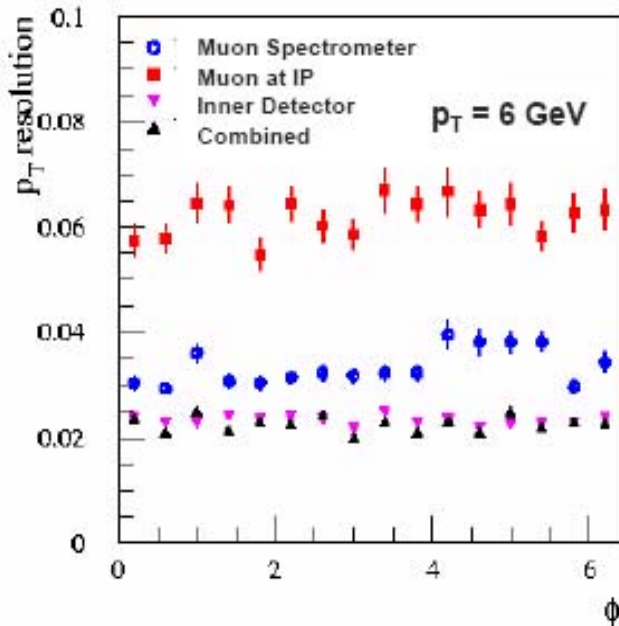

for $p_T=100$ GeV

a theoretical prediction of the momentum resolution curve, averaged over the ϕ -angle, as a function of η
 Complicating items that have been taken into account are the

- three-dimensional magnetic field,
- resolution on position measurements,
- detailed chamber layout, and
- a simplified material distribution in order to take material effects into account.

Single Muons: p_T Resolution Vs ϕ

■ Uniform resolution Vs ϕ

■ Small effect in the feet region

Higgs (130) mass before applying constraint on the Z mass

H mass from MS after all cuts

H mass from ID after all cuts

H mass staco after all cuts

Higgs mass when applying constraint on the Z mass

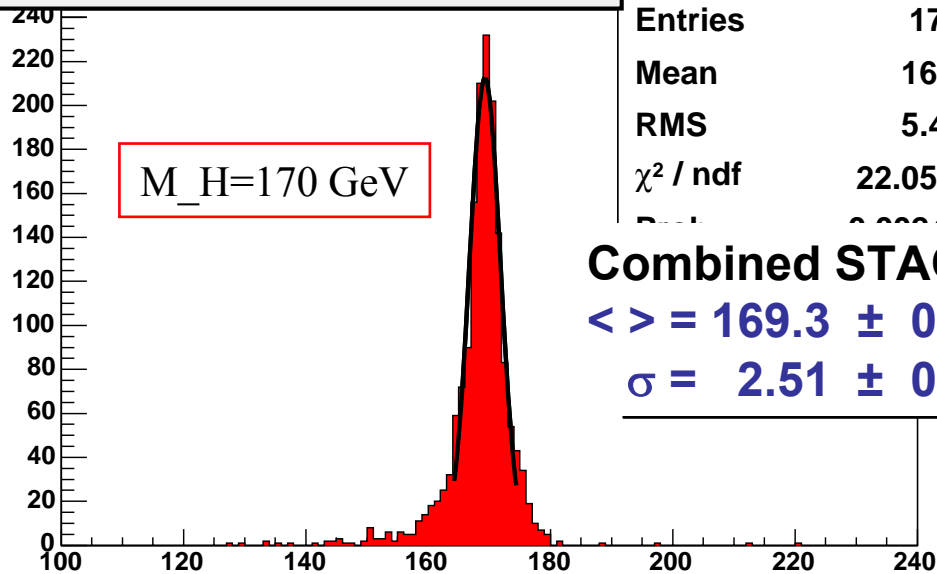

H with Z mass rescaling

H with Z mass rescaling

H with Z mass rescaling

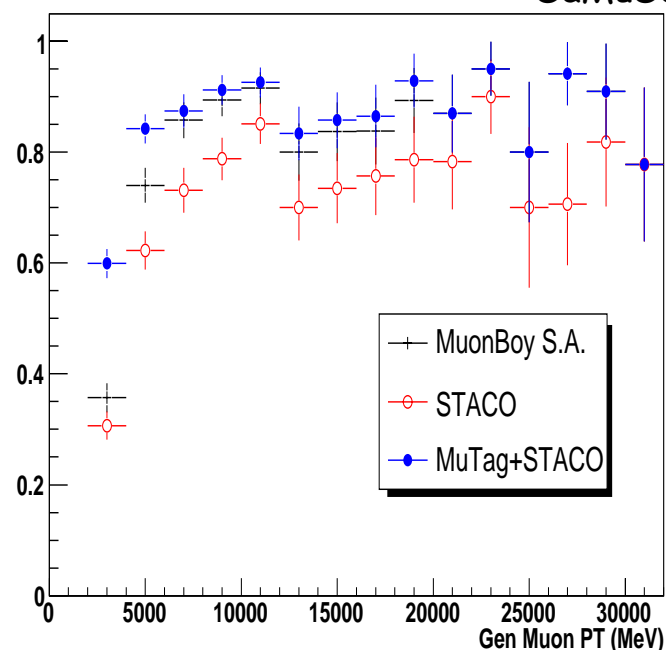

Potential of low-pT Algorithms as a Soft Muon b-tagger

- Study STACO / MuTag performance in jet environment
- Use (WH, mH=120GeV, H→bb̄) rmc samples

Efficiency (Muons from B), Barrel

Efficiency (Muons from B), Forward

SaMuSoG

High efficiency of STACO/MuTag down to $p \sim 4\text{GeV}$ in jets

Keeping in mind

- ‡ Muon reconstruction efficiency and resolution depends on the knowledge of the following effects :
 - ‡ Chambers Positions (Alignment)
 - ‡ Chamber Deformations (Including Temperature Effects)
 - ‡ Wire Sag
 - ‡ T₀, R-T Relations
 - ‡ B Field
 - ‡ Dead / Noisy / Anomalous Channels
 - ‡ neutron / γ Cavern Background
 - ‡ Geometric Material Distribution
 - ‡ Reconstruction Algorithm Optimization
- ‡ We plan to address all of these issues before LHC start-up.

Conclusions

- ▶ A **robust and reliable muon identification and momentum measurement** is crucial to fully exploit the physics potential of LHC over a large momentum range, starting from few GeV (B-physics study) to few TeV, where the presence of new physics might be expected.
- ▶ Atlas Muon spectrometer presents *complementary designs with large pseudorapidity coverage* ($|\eta| < 2.7$ for track reconstruction)
- ▶ **Magnetic Field configuration** determines the main features of the MS:
 - ▶ good p_T resolution up to high η → air-core toroids: low bending power → very good resolution of the muon chambers, alignment and calibration are crucial items
 - ▶ Flat resolution in η , $\sigma p_T/p_T$ of few % up to 100 GeV/c
- ▶ **Muon Reconstruction Algorithms** follow similar approaches: local reconstruction of segments in the multi-layer chambers, then extrapolated in defined detector regions.
 - ▶ standalone track reconstruction in the spectrometer, then matching with inner detector tracks

▶ Muon CSC notes studying

- ▶ the **effects of misalignment, magnetic field and miscalibration of the MDT-chambers** on the efficiency, fake-rate and momentum resolution of the ATLAS Muon Spectrometer.
- ▶ In a first step these effects are estimated on the basis of Monte-Carlo Truth information to provide an overview of the importance of these effects and a limit to which these effects must be understood to achieve the required performance.
- ▶ In a second step we study different approaches to determine the resolution and the efficiency of the ATLAS Muon Spectrometer with data only not relying on any MC information.
- ▶ These methods are based on the one hand on the study of well known resonances and their decay into two muons like $Z \rightarrow \mu\mu$ or $\Upsilon \rightarrow \mu\mu$ and $J/\Psi \rightarrow \mu\mu$ and on the other hand on in-situ use of single muons.
- ▶ How to the presented methods for the correction of misalignment and miscalibration of the MDT-chambers.

A big effort is now concentrating on tuning geometry model, simulation (detectors and trigger), calibration, tracking, event-selection and analysis and on preparing detector commissioning before the data taking startup, with the very good collaboration with Muon Simulation Team

MuonSimulation Plans of Mis-Alignment

- ❑ Plans for Release 13
 - ❑ Larger Random Displacements
 - ❑ σ_θ up to 3 mrad and σ_{xyz} up to 4 mm
 - ❑ Global Barrel and Big Wheel displacements
 - ❑ Details Under Discussion
 - ❑ Additional Inert Material Descriptions
 - ❑ Saddle, Big Wheel Supports, ID Patch Panel, Access Platforms
 - ❑ Resolution of Some GEANT4 Issues
 - ❑ Handling Complex Chamber Shapes without Using Up Allotted Memory
 - ❑ A More realistic implementation of Cavern Background in GEANT4
- ❑ Not for GEANT4
 - ❑ Chamber deformations (sag, torsion, cross-plate expansions, global temperature expansion...etc)
 - ❑ Deformation Corrections to be applied at Reconstruction

- the Organizers of this School, for inviting me to give this talk

A 3D cutaway diagram of the ATLAS detector, showing its complex internal structure. The detector is cylindrical and composed of several concentric layers. The outermost layer is the calorimeter, followed by the inner tracking detector. The central region contains the interaction point where collisions occur. The text "BACKUP SLIDES" is overlaid in the center of the diagram.

BACKUP SLIDES

ATLAS Conventional Coordinate System

- ❑ **z-axis** directed along the tunnel (beam axis)
- ❑ **x-y** define the plane perpendicular to the beam direction
- ❑ **x-axis** pointing from the interaction point to the center of the LHC ring
- ❑ Given the symmetry, **cylindrical coordinates** are more useful : φ, θ, R
- ❑ Instead of the polar angle θ , the so called **pseudorapidity** η is often used:
 - ❑ $\eta = -\ln(\tan(\theta/2))$

ATLAS Offline Software

□ Requirements

- Description of geometry and Event
- Visualization
- Simulation of detector
- Reconstruction of physical objects starting from raw data
 - output by the Event Filter (The final level of the Atlas Trigger) with <1.5 MB> arriving at a rate of about 200 Hz.
 - The data format is a "**byte-stream**" - that is a organized set of packed bits containing all the information about the event
- Data store - Data analysis

□ Characteristics

- High complexity
- Long lifetime of the experiment (20 years)
- Large Data Volume (1 Pbyte/years)
- Several Developers - Scattered all around the world

□ Need of

- Flexibility, abstraction, maintainability, uniformity, modularity, reusability, computing mechanism and development distributed.

□ Development of a software framework common to all the applications:

- ATHENA (ATLAS realization of a High Energy and Nuclear physics data analysis Architecture)
 - Detector Geometry, Data Description and Maintenance, Calibration Services, Databases, Simulation, Reconstruction.
 - Choice of using GRID technology
