$R_K^{(*)}$ in Standard Model

$$R_K = \frac{BR(B \to K\mu^+\mu^-)}{BR(B \to Ke^+e^-)}, \qquad R_{K^*} = \frac{BR(B \to K^*\mu^+\mu^-)}{BR(B \to K^*e^+e^-)}.$$

These are rare decays (each BR $\sim \mathcal{O}(10^{-7})$) because they are absent at tree level in SM.

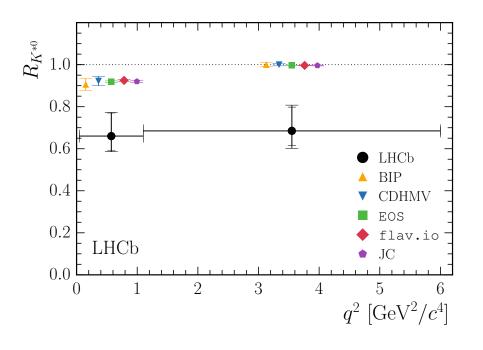

LHCb $B^0 \to K^{0^*} e^+ e^-$ Event¹

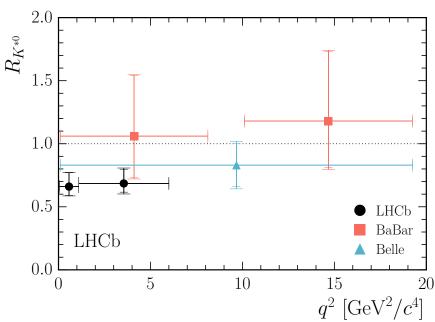

$R_{K^{(*)}}$ pre Moriond 2019

LHCb results from 7 and 8 TeV: $q^2 = m_{ll}^2$.

	q^2/GeV^2	SM	LHCb 3 fb^{-1}	σ
R_K	$\boxed{[1,6]}$	1.00 ± 0.01	$0.745^{+0.090}_{-0.074}$	2.6
R_{K^*}	[0.045, 1.1]	0.91 ± 0.03	$0.66^{+0.11}_{-0.07}$	2.2
R_{K^*}	[1.1, 6]	1.00 ± 0.01	$0.69^{+0.11}_{-0.07}$	2.5

R_K post Moriond 2019

LHCb results from 7, 8 and 13 TeV: $q^2 = m_{ll}^2$.

q^2/GeV^2			σ
R_K	[1.1, 6]	$0.745^{+0.090}_{-0.074} \ 0.846 \pm 0.06 \pm 0.02$	2.62.5

Breakdown: In Run II data up to end 2016 only:

$$R_K = 0.93 \pm 0.09$$

Reanlysing Run I data with new tweaked analysis

$$R_K = 0.745_{-0.074}^{+0.090}$$
 $0.717 \pm 0.08.$

There is still half of Run II data to analyse.

Wilson Coefficients $ar{c}_{ij}^l$

In SM, can form an EFT since $m_B \ll M_W$:

$$\mathcal{O}_{ij}^{l} = (\bar{s}\gamma^{\mu}P_{i}b)(\bar{l}\gamma_{\mu}P_{j}l).$$

$$\mathcal{L}_{\text{eff}} \supset \sum_{l=e,\mu,\tau} \sum_{i=L,R} \sum_{j=L,R} \frac{c_{ij}^{l}}{\Lambda_{l,ij}^{2}} \mathcal{O}_{ij}^{l},$$

$$= \sum_{l=e,\mu,\tau} V_{tb}V_{ts}^{*} \frac{\alpha}{4\pi v^{2}} \left(\bar{c}_{LL}^{l}\mathcal{O}_{LL}^{l} + \bar{c}_{LR}^{l}\mathcal{O}_{LR}^{l} + \bar{c}_{RL}^{l}\mathcal{O}_{RL}^{l} + \bar{c}_{RR}^{l}\mathcal{O}_{RR}^{l}\right)$$

$$\Rightarrow \bar{c}_{ij}^{l} = (36 \text{ TeV}/\Lambda)^{2} c_{ij}^{l}.$$

 $c_{ij}^l \sim \pm \mathcal{O}(1)$ all predicted by weak interactions in SM.

Which Ones Work?

Options for a single BSM operator:

- \bar{c}^e_{ij} operators fine for $R_{K^{(*)}}$ but are disfavoured by global fits including other observables.
- ullet $ar{c}_{LR}^{\mu}$ disfavoured: predicts enhancement in both R_K and R_{K^*}
- \bar{c}_{RR}^{μ} , \bar{c}_{RL}^{μ} disfavoured: they pull R_K and R_{K^*} in *opposite* directions.
- $\bar{c}_{LL}^{\mu} = -1.33 1.06$ fits well globally².

²D'Amico et al, 1704.05438; Aebischer et al 1903.10434.

Simplified Models for c_{LL}^{μ}

At tree-level, we have:

$B_s - \bar{B}_s$ Mixing

from QCD sum rules and lattice⁴

⁴King, Lenz, Rauh, arXiv:1904.00940

$Z' ightarrow \mu \mu$ ATLAS 13 TeV 139 ${ m fb}^{-1}$

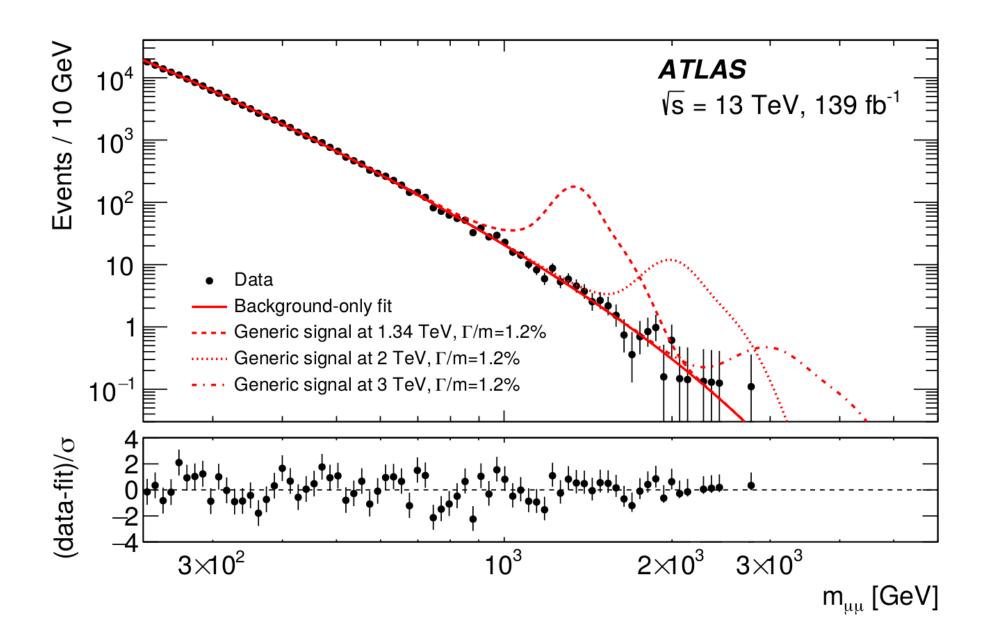

ATLAS analysis: look for two track-based isolated μ , $p_T>30$ GeV. One reconstructed primary vertex. Keep only highest scalar sum p_T pair⁵

$$m_{\mu_1\mu_2}^2 = (p_1^{\mu} + p_2^{\mu}) (p_{1\mu} + p_{2\mu})$$

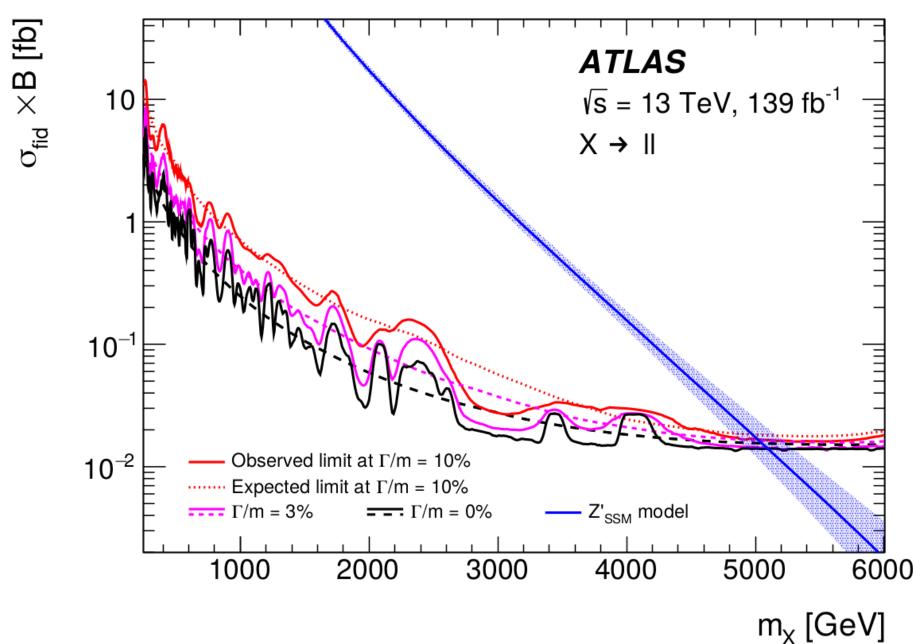

CMS also have released⁶ a similar 36 fb⁻¹ analysis.

⁵1903.06248

⁶1803.06292

ATLAS l^+l^- limits

Simplified Z' Models

Naïve model: only include couplings to $\bar{b}s/b\bar{s}$ and $\mu^+\mu^-$ (less model dependent).

$$\mathcal{L}_{Z'}^{\text{min.}} \supset \left(g_L^{sb} Z_{
ho}' \bar{s} \gamma^{
ho} P_L b + \text{h.c.}\right) + g_L^{\mu\mu} Z_{
ho}' \bar{\mu} \gamma^{
ho} P_L \mu \,,$$

which contributes to the \mathcal{O}^μ_{LL} coefficient with 7

$$ar{c}_{LL}^{\mu} = -rac{4\pi v^2}{lpha_{\mathsf{EM}} V_{tb} V_{ts}^*} rac{g_L^{sb} g_L^{\mu\mu}}{M_{Z'}^2},$$

$$\Rightarrow \left| g_L^{sb} g_L^{\mu\mu} \left(\frac{36 \text{ TeV}}{M_{Z'}} \right)^2 = -1.33 \pm 0.34 - 1.06 \pm 0.16. \right|$$

⁷Aebischer et al, arXiv:1903.10434

Simplified Z' Models⁸

$$\mathcal{L}_{Z'f} = \left(\overline{\mathbf{Q}'_{\mathbf{L}i}}\lambda_{ij}^{(Q)}\gamma^{\rho}\mathbf{Q'_{\mathbf{L}j}} + \overline{\mathbf{L}'_{\mathbf{L}i}}\lambda_{ij}^{(L)}\gamma^{\rho}\mathbf{L'_{\mathbf{L}j}}\right)Z'_{\rho},$$

After CKM mixing of $V=V_{u_L^\dagger}V_{d_L}$ and PMNS $U=V_{\nu_L}^\dagger V_{e_L}$,

$$\mathcal{L} = \left(\overline{\mathbf{u}_{\mathbf{L}}} V \Lambda^{(Q)} V^{\dagger} \gamma^{\rho} \mathbf{u}_{\mathbf{L}} + \overline{\mathbf{d}_{\mathbf{L}}} \Lambda^{(Q)} \gamma^{\rho} \mathbf{d}_{\mathbf{L}} + \overline{\nu}_{\mathbf{L}} U \Lambda^{(L)} U^{\dagger} \gamma^{\rho} \nu_{\mathbf{L}} + \overline{\mathbf{e}_{\mathbf{L}}} \Lambda^{(L)} \gamma^{\rho} \mathbf{e}_{\mathbf{L}} \right) Z_{\rho}',$$

where

$$\Lambda^{(Q)} \equiv V_{d_L}^{\dagger} \lambda^{(Q)} V_{d_L}, \qquad \Lambda^{(L)} \equiv V_{e_L}^{\dagger} \lambda^{(L)} V_{e_L}.$$

⁸BCA, Corbett, Dolan, You, arXiv:1810.02166

Limiting Cases

Mixed Up Model: all quark mixing is in left-handed ups

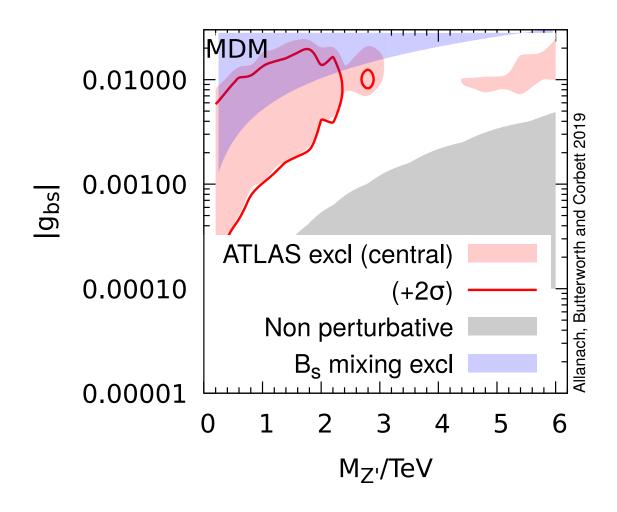

$$\Lambda^{(Q)} = g_{bs} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \qquad \Lambda^{(L)} = g_{\mu\mu} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

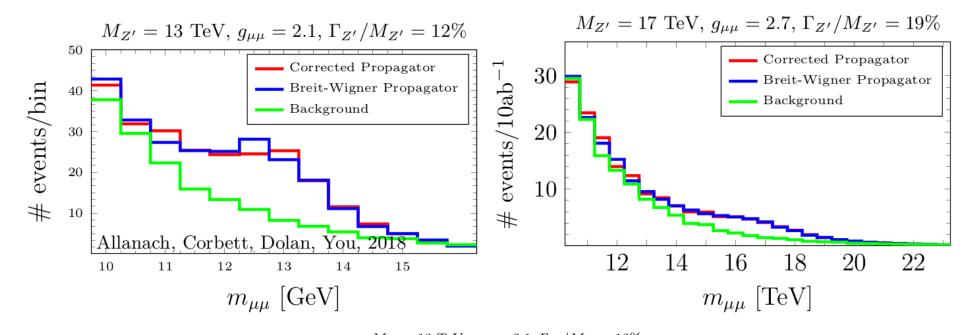

Mixed Down Model: all quark mixing is in left-handed downs

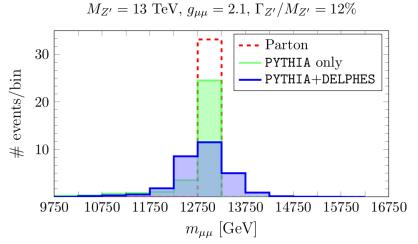

$$\Lambda^{(Q)} = g_{tt} V^{\dagger} \cdot \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot V, \qquad \Lambda^{(L)} = g_{\mu\mu} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

 $\Rightarrow g_{bs} = V_{ts}^* V_{tb} g_{tt} \approx -0.04 g_{tt}$: the quark couplings are weaker than the leptonic ones

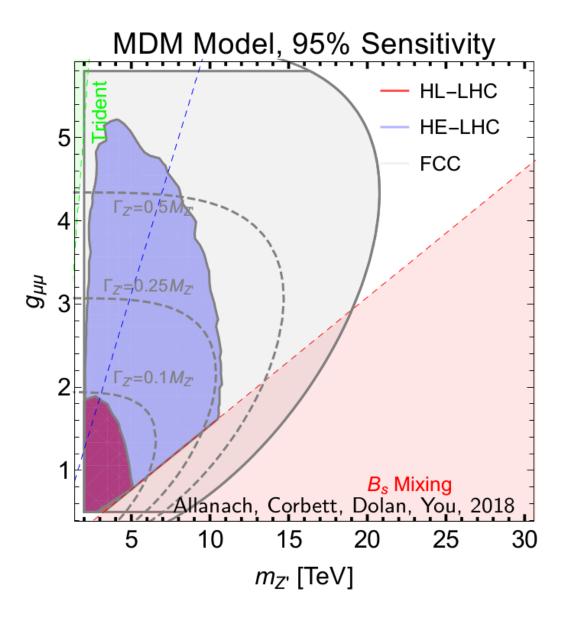

ATLAS $\mu\mu$ Constraint: MDM

During the 1990s

We wanted to be the Grand Architects, searching for **the** string model to rule them all

During the 2010s

We are happy with **any** beyond the Standard Model roof

Third Family Hypercharge Model

Add complex SM singlet scalar θ and gauged $U(1)_F$:

$$SU(3) \times SU(2)_L \times U(1)_Y \times U(1)_F$$
 $\langle \theta \rangle \sim$ Several TeV $SU(3) \times SU(2)_L \times U(1)_Y$ $\langle H \rangle \sim$ 246 GeV $SU(3) \times U(1)_{em}$

- SM fermion content
- anomaly cancellation
- 0 F charges for first two generations

Unique Solution

$$\mathcal{L} = Y_t \overline{Q_{3L}'} H t_R' + Y_b \overline{Q_{3L}'} H^c b_R' + Y_\tau \overline{L_{3L}'} H^c \tau_R' + H.c.,$$

- First two families massless at renormalisable level
- Their masses and fermion mixings generated by small non-renormalisable operators

This explains the hierarchical heaviness of the third family and small CKM angles

Z-X mixing

Because $F_H = -1/2$, Z - X mix:

$$\mathcal{M}_{N}^{2} = \frac{v^{2}}{4} \begin{pmatrix} g'^{2} & -gg' & g'g_{F} \\ -gg' & g^{2} & -gg_{F} \\ g'g_{F} & -gg_{F} & g_{F}^{2}(1+4F_{\theta}^{2}r^{2}) \end{pmatrix} \begin{pmatrix} -B_{\mu} \\ -W_{\mu}^{3} \\ -X_{\mu} \end{pmatrix}$$

- $v \approx 246$ GeV is SM Higgs VEV
- $g_F = U(1)_F$ gauge coupling
- $r \equiv v_F/v \gg 1$, where $v_F = \langle \theta \rangle$
- F_{θ} is F charge of θ field

Z-X mixing angle

$$\sin \alpha_z \approx \frac{g_F}{\sqrt{g^2 + g'^2}} \left(\frac{M_Z}{M_Z'}\right)^2 \ll 1.$$

This gives small non-flavour universal couplings to the Z boson propotional to g_F and:

$$Z_{\mu} = \cos \alpha_z \left(-\sin \theta_w B_{\mu} + \cos \theta_w W_{\mu}^3 \right) + \sin \alpha_z X_{\mu},$$

$$\mathcal{L}_{X\psi} = g_{F} \left(\frac{1}{6} \overline{\mathbf{u}_{\mathbf{L}}} \Lambda^{(u_{L})} \gamma^{\rho} \mathbf{u}_{\mathbf{L}} + \frac{1}{6} \overline{\mathbf{d}_{\mathbf{L}}} \Lambda^{(d_{L})} \gamma^{\rho} \mathbf{d}_{\mathbf{L}} - \frac{1}{2} \overline{\mathbf{n}_{\mathbf{L}}} \Lambda^{(n_{L})} \gamma^{\rho} \mathbf{n}_{\mathbf{L}} - \frac{1}{2} \overline{\mathbf{e}_{\mathbf{L}}} \Lambda^{(e_{L})} \gamma^{\rho} \mathbf{e}_{\mathbf{L}} + \frac{2}{3} \overline{\mathbf{u}_{\mathbf{R}}} \Lambda^{(u_{R})} \gamma^{\rho} \mathbf{u}_{\mathbf{R}} - \frac{1}{3} \overline{\mathbf{d}_{\mathbf{R}}} \Lambda^{(d_{R})} \gamma^{\rho} \mathbf{d}_{\mathbf{R}} - \overline{\mathbf{e}_{\mathbf{R}}} \Lambda^{(e_{R})} \gamma^{\rho} \mathbf{e}_{\mathbf{R}} \right) Z_{\rho}',$$

$$\Lambda^{(I)} \equiv V_{I}^{\dagger} \xi V_{I}, \qquad \xi = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Z' couplings, $I \in \{u_L, d_L, e_L, \nu_L, u_R, d_R, e_R\}$

Example Case

Take a simple limiting case:

$$V_{u_R} = V_{d_R} = V_{e_R} = 1$$

for simplicity and the ease of passing bounds.

$$V_{d_L} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta_{sb} & -\sin \theta_{sb} \\ 0 & \sin \theta_{sb} & \cos \theta_{sb} \end{pmatrix}, \qquad V_{e_L} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix},$$

$$\Rightarrow V_{u_L} = V_{d_L} V_{CKM}^\dagger$$
 and $V_{
u_L} = V_{e_L} U_{PMNS}^\dagger$.

Important Z' Couplings

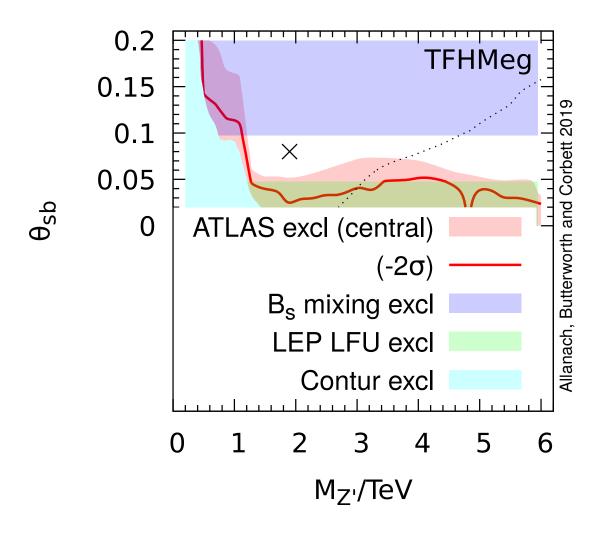

$$g_{F} \begin{bmatrix} \frac{1}{6} \overline{\mathbf{d}_{L}} \begin{pmatrix} 0 & 0 & 0 \\ 0 & \sin^{2} \theta_{sb} & \frac{1}{2} \sin 2\theta_{sb} \\ 0 & \frac{1}{2} \sin 2\theta_{sb} & \cos^{2} \theta_{sb} \end{pmatrix} Z' \begin{pmatrix} d_{L} \\ s_{L} \\ b_{L} \end{pmatrix} +$$

$$-\frac{1}{2}\overline{\mathbf{e_L}} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \mathbf{Z}' \begin{pmatrix} e_L \\ \mu_L \\ \tau_L \end{pmatrix} \right]$$

Put $|\theta_{sb}| \sim \mathcal{O}(|V_{ts}|) = 0.04$, so $|g_{\mu\mu}| \gg |g_{bs}|$, which helps us survive $B_s - \overline{B_s}$ constraint.

$$c_{LL} = g_F^2 \sin 2\theta_{sb} / (24M_{Z'}^2).$$

$g_F \propto M_{Z'}/\sqrt{\sin 2\theta_{bs}}$

Example Case Predictions

Mode	BR	Mode	BR	Mode	BR
\overline{t}	0.42	$b\overline{b}$	0.12	$ u \bar{ u}'$	0.08
$\mu^+\mu^-$	80.0	$\mid au^+ au^- \mid$	0.30	other f_if_j	$\sim \mathcal{O}(10^{-4})$

LEP LFU

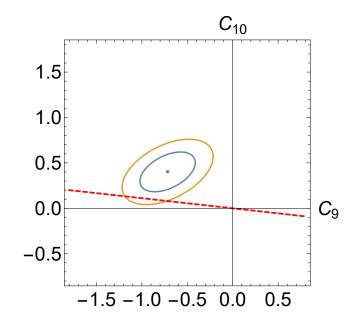

$$g_F^2 \left(\frac{M_Z}{M_{Z'}}\right)^2 \le 0.004 \Rightarrow g_F \le \frac{M_{Z'}}{1.3 \text{ TeV}}.$$

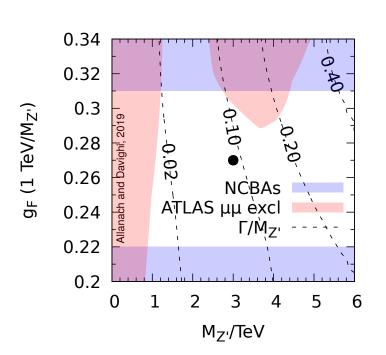

It's worth LHCb, BELLE II chasing $BR(B \to K^{(*)}\tau^{\pm}\tau^{\mp})$.

Deformed TFHM

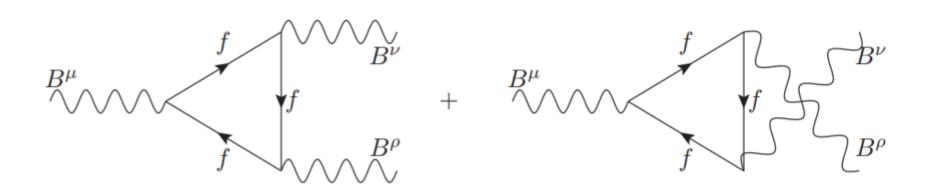

$$\begin{aligned} F_{Q_i'} &= 0 & F_{u_{R_i'}} &= 0 & F_{d_{R_i'}} &= 0 & F_{H} &= -1/2 \\ F_{e_{R_1'}} &= 0 & F_{e_{R_2'}} &= 2/3 & F_{e_{R_3'}} &= -5/3 \\ F_{L_1'} &= 0 & F_{L_2'} &= 5/6 & F_{L_3'} &= -4/3 \\ F_{Q_3'} &= 1/6 & F_{u_{R_3}'} &= 2/3 & F_{d_{R_3}'} &= -1/3 & F_{\theta} \neq 0 \end{aligned}$$

$$\mathcal{L} = Y_t \overline{Q_{3L}'} H t_R' + Y_b \overline{Q_{3L}'} H^c b_R' + H.c.,$$

Quantum Field Theory Anomalies

$$A \equiv \sum_{LH \ f_i} Y_i^3 - \sum_{RH \ f_i} Y_i^3$$

Hypercharge anomaly cancellation

Deforming the SM to $SU(3) \times SU(2) \times \mathbb{R}_Y$, and allowing the hypercharges Y of the chiral fermionic fields to float, the combination of gauge ACC and gravitational ACC implies that the hypercharges must be quantised⁹ (i.e. that ratios of hypercharges of different chiral fermions are rational). Conversely, if the hypercharges are quantised but otherwise free, the gauge ACC implies the gravitational ACC 10 .

⁹Weinberg, The Quantum Theory of Fields (1995), CUP

¹⁰Lohitsiri and Tong, arXiv:1907.00514

Anomaly equations

4 linear ones, and

$$\sum_{i=1}^{3} (F_{Q_i}^2 - F_{L_i}^2 - 2F_{u_i}^2 + F_{d_i}^2 + F_{e_i}^2) = 0,$$

ACC is the cubic

$$\sum_{i=1}^{3} (6F_{Q_i}^3 + 2F_{L_i}^3 - 3F_{u_i}^3 - 3F_{d_i}^3 - F_{e_i}^3 - F_{\nu_i}^3) = 0,$$

Look for solutions in rational numbers. Also, re-scaling invariance means that can re-scale to integers.

Solve case for 1 or 2 families of charges analytically, using old Diophantine methods. For 3 families, wrote a efficient computer program to search through $(2Q_{max}+1)^{18}$ sets of charges for SM and SM+3 ν_R , find all those that solve the anomaly equations.

Integer charges

We argue ratios of charges are *rationals*: in a holographic setting, boundary CFT is finitely generated (finite number of fields in path integral) then gauge group must be compact¹¹. Also, otherwise they wouldn't fit into some unified non-abelian group.

ACCs have rescaling invariance: so we can rescale rationals by highest denominator to obtain integers. Note that we shall *mod out* by the permutation invariance of switching a species family indices around in the ACCs by strictly ordering them.

SM solutions

An Anomaly-Free Atlas

The atlas is available for public use: http://doi.org/10.5281/zenodo.1478085

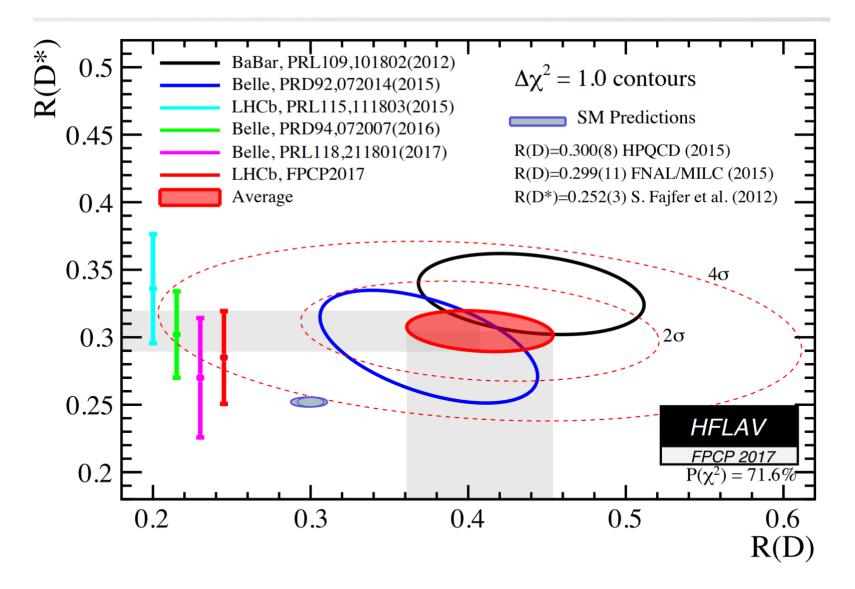

We did various checks (are solutions that were found in the literature before present, and are classes that have been banned not present?)

BCA, Davighi, Melville, arXiv:1812.04602

Conclusions

The answers to the questions raised by the neutral current B—anomalies may provide a direct experimental probe into the flavour problem.

$$R_{D^{(*)}} = BR(B^- \to D^{(*)}\tau\nu)/BR(B^- \to D^{(*)}\mu\nu)$$

$R_{D(*)}$: BSM Explanation

 $\sum_{w^+} \sum_{\tau^+} \sum_{q} \sum_{D/D^+} \overline{c}_{q}$... has to compete with

$$\mathcal{L}_{eff} = -rac{2}{\Lambda^2} \left(ar{c}_L \gamma^\mu b_L
ight) \left(ar{ au}_L \gamma_\mu
u_{ au L}
ight) + H.c.$$

$$\Lambda = 3.4 \text{ TeV}$$

A factor 10 lower than required for $R_{K^{(*)}} \Rightarrow$ different explanation?

PMP
$$\Rightarrow$$
we ignore $R_{D^{(*)}}$.

Other conclusions

- ullet The answers to the questions raise by $R_{K^{(*)}}$ may provide a direct experimental probe into the flavour problem.
- ullet Focused on tree-level explanations of $R_{K^{(*)}}$ as they are usually harder to discover: Z' and leptoquarks.
- News on $R_K^{(*)}$ expected in 2019. At the current central value, Belle II can reach 5σ by mid 2021. LHCb's R_{K^*} would be close to 12 5σ by 2020.
- ullet $R_{K^{(*)}} \Rightarrow$ HL-LHC, HE-LHC and FCC-hh

Neutrino Masses

At dimension 5:

$$\mathcal{L}_{SS} = \frac{1}{2M} (L_3'^T H^c) (L_3' H^c),$$

but if we add RH neutrinos, then integrate them out

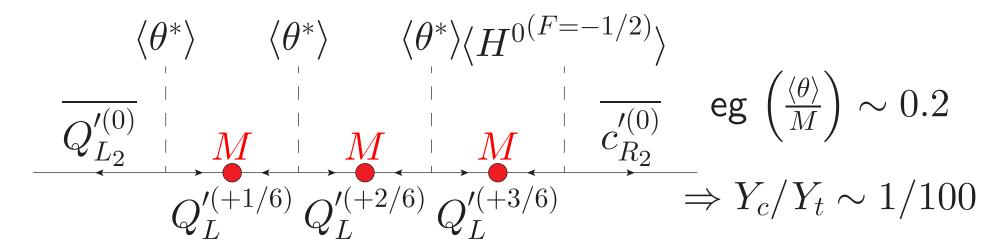

$$\mathcal{L}_{SS} = 1/2 \sum_{ij} (L_i' H^c) (M^{-1})_{ij} (L_j' H^c),$$

where now $(M^{-1})_{ij}$ may well have a non-trivial structure. If $(M^{-1})_{ij}$ are of same order, large PMNS mixing results.

Froggatt Neilsen Mechanism¹³

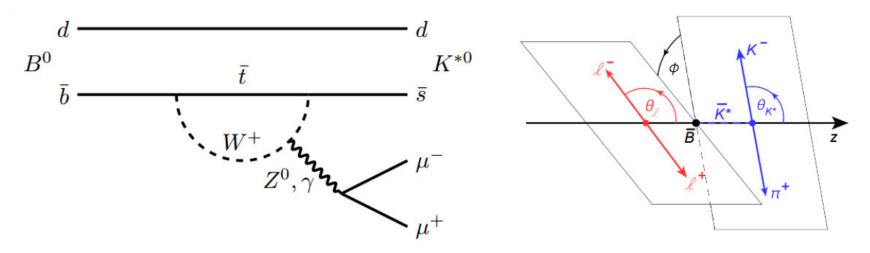

A means of generating the non-renormalisable Yukawa terms, e.g. $F_{\theta} = 1/6$:

$$Y_c \overline{Q_{L2}^{\prime}}^{(F=0)} H^{(F=-1/2)} c_R^{\prime}^{(F=0)} \sim \mathcal{O} \left[\left(\frac{\langle \theta \rangle}{M} \right)^3 \overline{Q_{L2}^{\prime}} H c_R^{\prime} \right]$$

¹³C Froggatt and H Neilsen, NPB**147** (1979) 277

$B^0 \to K^{*0} (\to K^+ \pi^-) \mu^+ \mu^-$

Decay fully described by three helicity angles $\vec{\Omega}=(\theta_\ell,\theta_K,\phi)$ and $q^2=m_{\mu\mu}^2$

$$\frac{1}{\mathrm{d}(\Gamma + \bar{\Gamma})/\mathrm{d}q^2} \frac{\mathrm{d}^3(\Gamma + \bar{\Gamma})}{\mathrm{d}\bar{\Omega}} = \frac{9}{32\pi} \left[\frac{3}{4} (1 - F_{\mathrm{L}}) \sin^2 \theta_K + F_{\mathrm{L}} \cos^2 \theta_K + \frac{1}{4} (1 - F_{\mathrm{L}}) \sin^2 \theta_K \cos 2\theta_\ell \right.$$

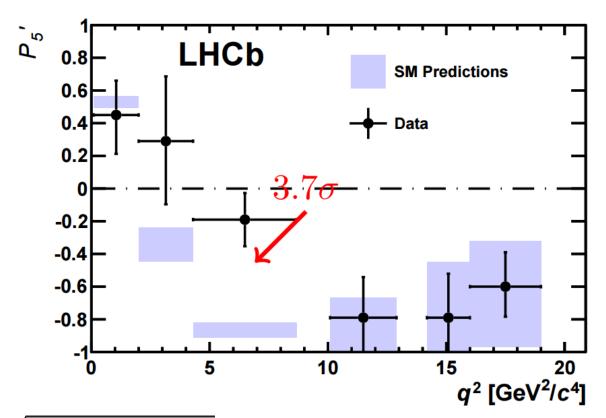

$$- F_{\mathrm{L}} \cos^2 \theta_K \cos 2\theta_\ell + S_3 \sin^2 \theta_K \sin^2 \theta_\ell \cos 2\phi$$

$$+ S_4 \sin 2\theta_K \sin 2\theta_\ell \cos \phi + S_5 \sin 2\theta_K \sin \theta_\ell \cos \phi$$

$$+ \frac{4}{3} A_{\mathrm{FB}} \sin^2 \theta_K \cos \theta_\ell + S_7 \sin 2\theta_K \sin \theta_\ell \sin \phi$$

$$+ S_8 \sin 2\theta_K \sin 2\theta_\ell \sin \phi + S_9 \sin^2 \theta_K \sin^2 \theta_\ell \sin 2\phi \right]$$

 $P_5' = S_5/\sqrt{F_L(1-F_L)}$, leading form factor uncertainties cancel. Tension already in 1 fb⁻¹ and confirmed in 3 fb⁻¹ LHCb-CONF-2015-002

Hadronic Uncertainties

► Hadronic effects like charm loop are photon-mediated ⇒ vector-like coupling to leptons just like C₉

- ► How to disentangle NP ↔ QCD?
 - ► Hadronic effect can have different q² dependence
 - ▶ Hadronic effect is lepton flavour universal ($\rightarrow R_K!$)

LQ Models

Scalar¹⁴ $S_3 = (\bar{3}, 3, 1/3)$ of $SU(2) \times SU(2)_L \times U(1)_Y$:

$$\mathcal{L} = \ldots + y_{3b\mu}Q_3L_2S_3 + y_{3s\mu}Q_2L_2S_3 + y_qQQS_3^{\dagger} + \text{h.c.}$$

Vector
$$V_1 = (\bar{3}, 1, 2/3)$$
 or $V_3 = (3, 3, 2/3)$

$$\mathcal{L} = \ldots + y_3' V_3^\mu \bar{Q} \gamma_\mu L + y_1 V_1^\mu \bar{Q} \gamma_\mu L + y_1' V_1^\mu \bar{d} \gamma_\mu l + \text{h.c.}$$

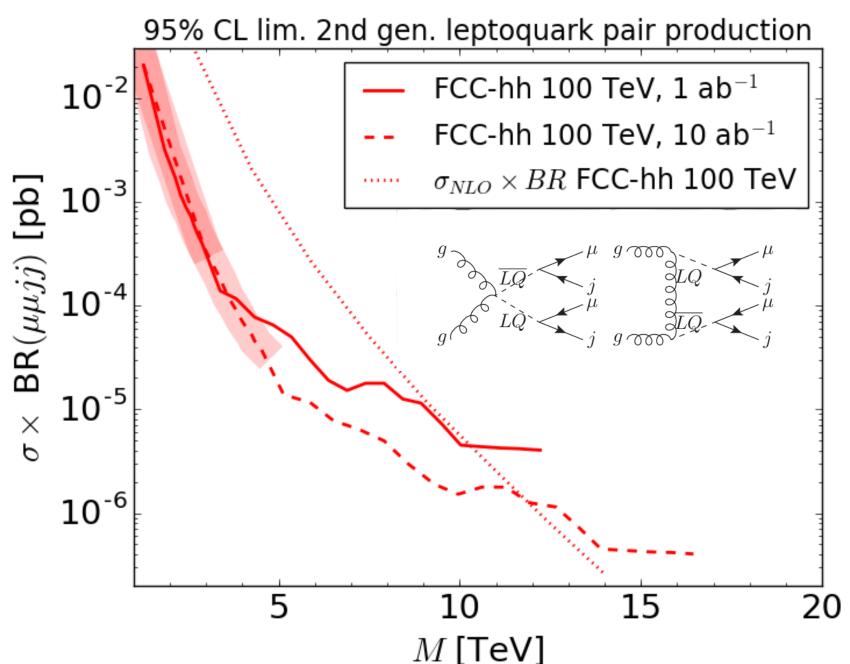

$$\Rightarrow \bar{c}_{LL}^{\mu} = \kappa \frac{4\pi v^2}{\alpha_{\text{EM}} V_{tb} V_{ts}^*} \frac{y_{3b\mu}^* y_{3s\mu}}{M^2}.$$

$$\kappa = 1, -1, -1 \text{ and } y = y_3, y_1, y_3' \text{ for } S_3, V_1, V_3.$$

CMS 8 TeV 20fb $^{-1}$ 2nd gen

CMS-PAS-EX0-12-042: M > 1.07 TeV.

Other Constraints On LQs

Note that the extrapolation is very rough for pair production. Fix $M=2M_{LQ}$, assuming they are produced

close to threshold: $\Delta=0.1$.

mixing is at one-loop:

$$\mathcal{L}_{\bar{b}s\bar{b}s} = k \frac{|y_{b\mu}y_{s\mu}^*|^2}{32\pi^2 M_{LQ}^2} \left(\bar{b}\gamma_{\mu}P_L s\right) \left(\bar{s}\gamma^{\mu}P_L b\right) + \text{h.c.}$$

 $y=y_3,y_1,y_3'$ and k=5,4,20 for S_3,V_1,V_3 . Data $\Rightarrow c_{LL}^{bb} < 1/(210 {\rm TeV})^2$.

Mass Constraints: Summary

$$egin{array}{c|c} S_3 & 41 \ TeV \ V_1 & 41 \ TeV \ V_3 & 18 \ TeV \ \end{array}$$

Upper mass limits for leptoquarks that satisfy neutral current B-anomaly fits and B_s -mixing constraints.

8 TeV CMS $20 \mathrm{fb}^{-1}$ 2nd gen

Up to 14 TeV LQs with 100 TeV 10 ab $^{-1}$ FCC-hh. $M_{LQ} < 41$ TeV.

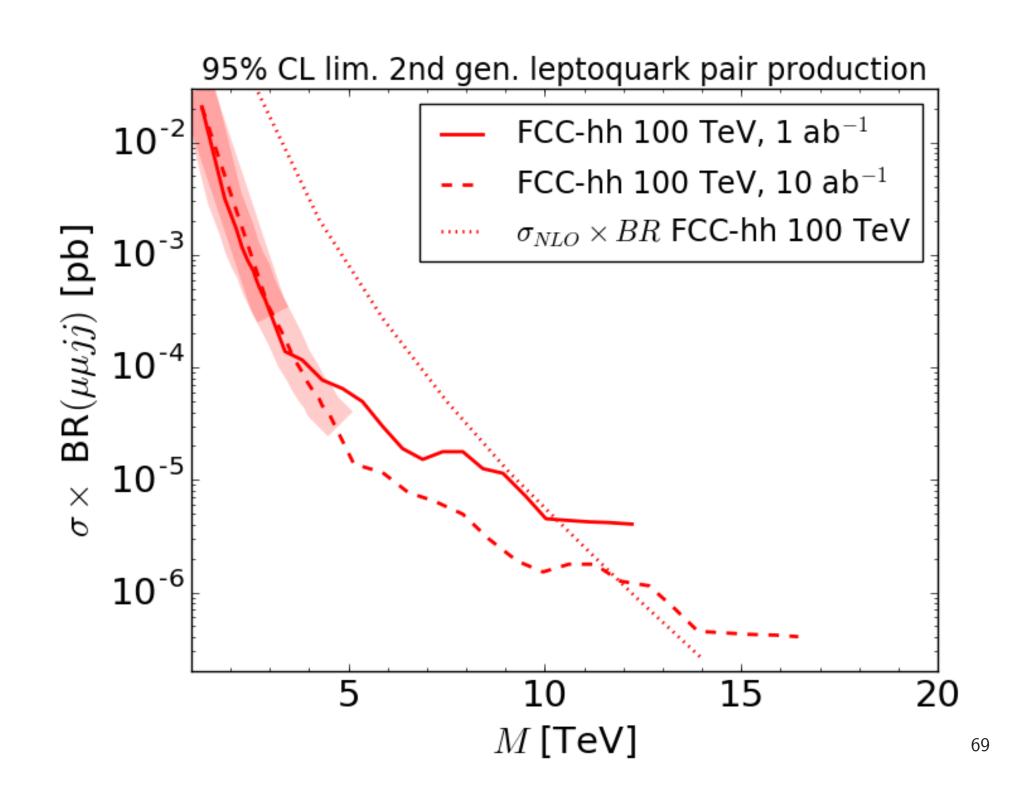

LQ Mass Limits

$$egin{array}{c|cccc} S_3 & 41 \ TeV \ V_1 & 41 \ TeV \ V_3 & 18 \ TeV \ \end{array}$$

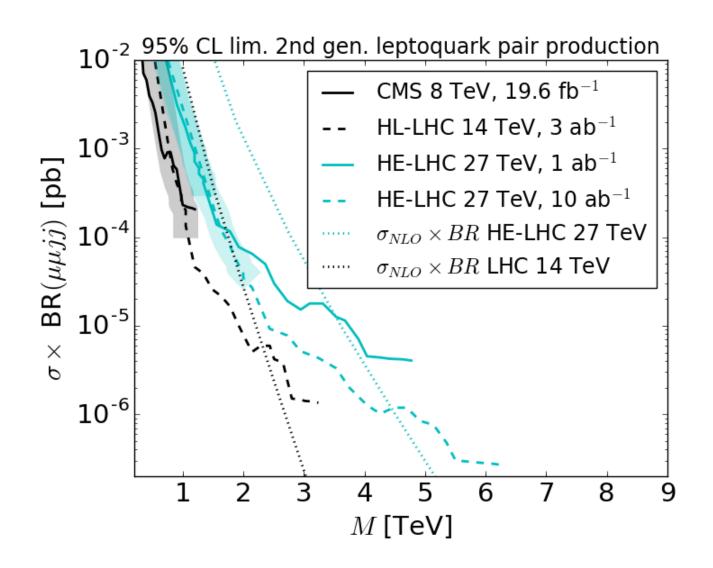

From $B_s - \bar{B}_s$ mixing and fitting b—anomalies.

Pair production has a reach up to 12 TeV.

The pair production cross-section is insensitive to the representation of SU(2) in this case.

HL-LHC/HE-LHC LQs

$$B_s \to \mu^+ \mu^-$$

Lattice QCD provides important input to

$$BR(B_s \to \mu\mu)_{SM} = (3.65 \pm 0.23) \times 10^{-9},$$

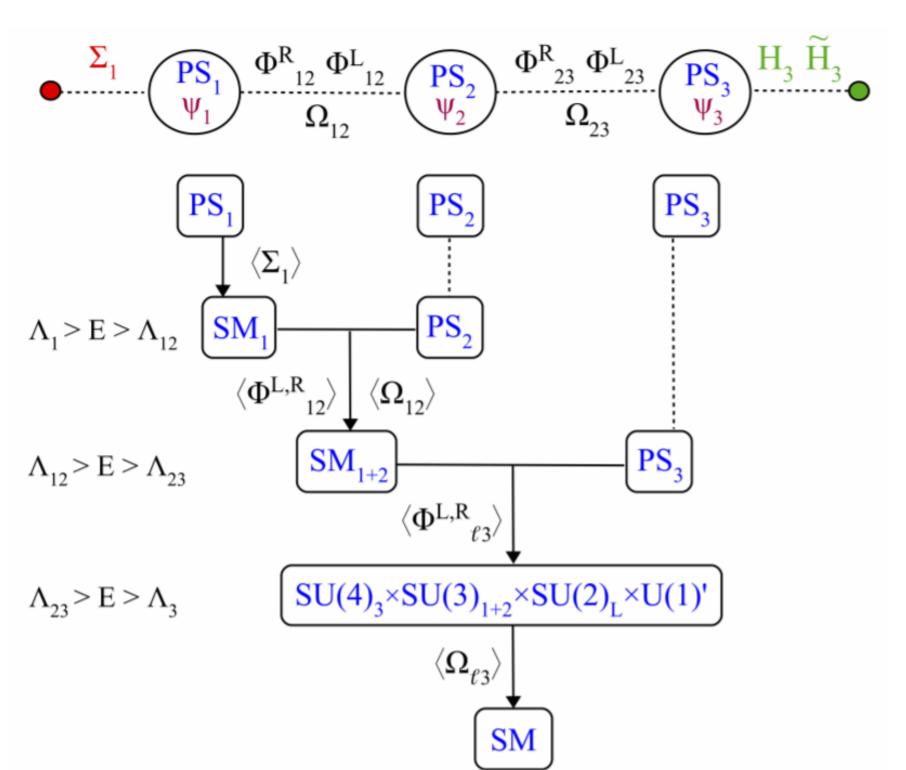

$$BR(B_s \to \mu\mu)_{exp}) = (3.0 \pm 0.6) \times 10^{-9}.$$

$$\frac{BR(B_s \to \mu\mu)}{BR(B_s \to \mu\mu)_{SM}} = \left| \frac{(\bar{c}_{LL}^{\mu} + \bar{c}_{RR}^{\mu} - \bar{c}_{LR}^{\mu} - \bar{c}_{RL}^{\mu})^{tot}}{(\bar{c}_{LL}^{\mu} + \bar{c}_{RR}^{\mu} - \bar{c}_{LR}^{\mu} - \bar{c}_{RL}^{\mu})^{SM}} \right|^{2}.$$

Other Flavour Models

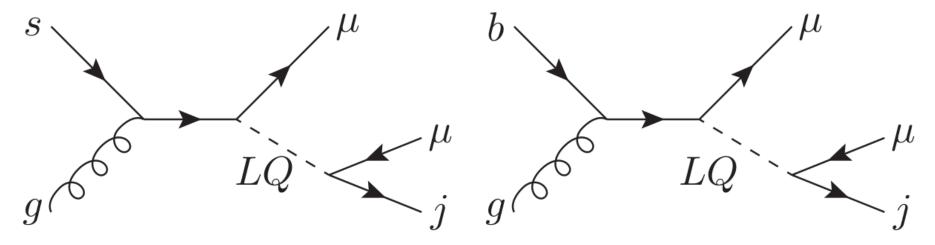

Realising¹⁵ the vector LQ solution based on $PS = [SU(4) \times SU(2)_L \times SU(2)_R]^3$. SM-like Higgs lies in third generation PS group, explaining large Yukawas (others come from VEV hierarchies). Get $U(2)_Q \times U(2)_L$ approximate global flavour symmetry.

Modelling the fourth colour: dispatch from de Moriond

At the particle physics conference, it's clear inconclusive LHCb data are stimulating strange new ideas

Sat 17 Mar 2018 10.15 GMT

In the middle of the Rencontres de Moriond particle physics conference in Italy, the scientific talks stopped to allow a standing ovation dedicated to the memory and achievements of my inspirational colleague Stephen Hawking, who we heard had died earlier that day.

The talks quickly resumed, which I think Stephen would have approved of. The most striking thing about the scientific content of the conference this year was that a whole day was dedicated to the weirdness in bottom particles that Tevong You and I wrote about last November. As Marco Nardecchia reviewed in his talk (PDF), bottom particles produced in the LHCb detector in proton collisions are decaying too often in certain particular ways, compared to predictions from the Standard Model of particle physics. Their decay products are coming out with the wrong angles too often compared with predictions, too.

Anomalous bottoms at Cern and the case for a new collider

We were hoping for an update on the data at the conference: the amount of data has roughly doubled since they were last released, and we need to see the new data to be convinced that something really new is happening in the collisions. I strongly suspect that if the effect is seen in the new data, the theoretical physics community will "go nuts" and we will quickly see the resulting avalanche of papers. If the new data look ordinary, the effect will be forgotten and everyone will move on. Taking such measurements correctly takes care and time, however, and the LHCb experiment didn't release them.

We shall have to wait until other conferences later this year for the LHCb to present its analyses of the new data.

There were interesting theory talks on how new forces could explain the strange properties of the bottom particle decays. The full mathematical models look quite baroque: they need a lot of "bells and whistles" in order to pass other experimental tests. But these models prove that it can be done, and they are quite different to what has been proposed before.

One of them even unifies different classes of particle (leptons and quarks), describing the lepton as the "fourth colour" of a quark. We are used to the idea that quarks come in three (otherwise identical) copies: physicists label them red, green and blue to distinguish them. As Javier Fuentes-Martin describe (PDF), once you design the mathematics to make leptons the fourth colour, the existence of a new force-carrying particle with just the correct properties to break up the
